Abstract:
Source: US2004210194A A thrombectomy catheter device having an improved hemostasis valve which is self−sealing and which functions as a one−way valve. The self−sealing hemostasis valve can be factory preset to automatically seal with or without the inclusion of a guidewire at a certain desired pressure or allowable leakage. Such sealing is automatic without the need to manually manipulate a hemostasis nut to obtain hemostasis. The thrombectomy catheter device can, without hemostasis nut adjustment, be positioned along and about a guidewire while yet maintaining suitable pressure for sustaining hemostasis at a preferred level. Certain embodiments of the thrombectomy catheter device having a self−sealing hemostasis valve include an adjustable hemostasis nut which can be manually tightened to restrict flow or guidewire movement or loosened to reduce friction on the guidewire and allow fluid to flow out if desired. An introducer facilitates free passage of a guidewire in either direction through the hemostasis nut and hemostasis valving and can also be incorporated to purge internal air or fluids.

Abstract:
Source: US2012089071A An implant device is configured to be implanted in a fistula to fluidly connect the lacrimal apparatus and a paranasal sinus. A surgical tool has an implant the implant device mounted on a carrier. Various methods involve a fistula between the lacrimal apparatus and a paranasal sinus. A kit includes an entry device for use to form a fistula and an implant tool for use to implant an implant device following formation of a fistula.

Abstract:
Source: US2002151906A Thrombectomy and other treatments are achieved using a catheter having a positioning cage and a macerator within the positioning cage. The catheter is introduced to a target body lumen, typically a blood vessel, and a positioning cage deployed at a treatment site. The macerator is then operated to disrupt thrombus, clot, or other occlusive materials at the treatment site, and the catheter is used to collect and remove the disruptive materials from the body lumen. In particular examples, the macerator may be radially expansible and optionally rotated and/or axially translated within the positioning cage to effect disruption of the occlusive material.

Abstract:
Source: US2015027204A A humidification system comprises a first sensor and a second sensor. The first and second sensors are adapted to sense flow characteristics within the system. The first and second sensors are isolated from the flow by barriers formed by respective first and second sealing members. The sealing members extend through apertures formed in the system and have a portion that contacts the sensing elements of the respective first and second sensors. A cartridge can hold the sensors and provide repeatable penetration depths into a flow passage of the system. A medical tube has a composite structure made of two or more distinct components that are spirally wound to form an elongate tube. One component can be a spirally wound elongate hollow body; the other component can be an elongate structural component spirally wound between turns of the spirally wound hollow body.

Abstract:
Source: US2009676A closure |'I_gt;1 to provide for the introduction of the liquid. In the operation of the device the charnber A constitutes a pressure chamber for resisting the upward movement of the piston I2 and thus checking reboundoi the vehicle springs while the chamber B serves as a pressure chamber to resist the downward movement of the piston 52 to check and control the compression of the vehicle springs. The features of construction byvwhich these functions are accornplished will now be explained. On comparison of Figs. 10, 11, 12 and 13 it will be observed that the shaft HE! of the piston is formed with a large axial bore 22 which extends substantially through the piston hub section of the shaft and opens through the end of the shaft section |2=. As shown in Fig. 13 the hub of the piston is formed with 9. radial passage 23 which leads from the pressure chamber A into an annular enlargement 22° of the axial bore 22. .And at approximately right angles to the passage 23 is a radial passage 24 in the hub of the piston, said passage leading from the axial passage 22 to the pressure chamber B, In the passage 24 is a spring pressed check valve 25 which permits Sow only in a radially outward direction through the passage EB. The conduit formed by the passages 23, 22 and 24 is controlled by a valve means comprising a valve body or valve proper 26. The valve body 26 which is made of metal is tubular In form with one endopen and the other closed. The open end 26° of the valve is of larger diameter than the closed end end 26a the plspart 25" annular bore 22. Junction portion 2v'5*=, the diameter of the larger being such as to nicely it the bore 22 of ton, while the diameter of the smaller is such as to afford a relatively large space between it and the wall of the The sharp annular shoulder 26° at the of the larger and smaller parts of the valve serves in conjunction with the wall of the annular enlargement 22" to nicely control liquid flow from the chamber A through the passages 23, 22 and 24 to the chamber B. The position of the valve in the passage 22 is determined by an elongated thermostatlc member 21 which serves in eEect as the stem of the valve. The valve stern or member 21 as shown is in the form of a slender cylinder or pencil of material having a. coeftlcient of thermal expansion ,differing largely from the metal composing the piston and its shaft. The material which I preferably employ for this purpose is ebonite which has a coefticient ,of expansion very much higher than that of iron or steel and is substantially unaffected by most liquids and chemicals. It will be noted that the valve stem 21' at one end its within the smaller section oi the valve 26, engaging the closed end of the latter, and from this point it extends throughout the length of the passage 22 and substantially through the shaft I3 which is bored out at 28 to receive it with an easy flt, the outer end of the bore being threaded to receive a screw plug 29 which serves as an adjustable abutment for the outer end of the valve stem. The plug 29 can be held in adjusted position by peenlng or by making it with a tight nt, At the inner end of the valve 25 and interposed between it `and the adjacent inner surface of the bearing boss Bl' is a four armed spring 30 which yieldingly presses the valve and the valve stem against the adjustable abutment 29. _ On reference to Figs. ll and 13 lt will be noted that the periphery of the hub portion ofathe piston is formed with a circumferentially `extending tapered groove 3| which communicates at its deeper end with a passage 32 extending radially inward from the groove 3| to the axial bore or passage 22; and diametrically opposite the passage 32 is a passage 33 leading from the passage Z2 into the pressure chamber A, this latter passage being controlled by a check valve 32 which opens radially outward and permits flow only in that direction. It will thus be seen that the groove 35, passage 32, passage 22 and passage 33 constitute a conduit ailording communication between the pressure chamber B and the pressure chamber A and that the effective capacity of this conduit varies with the angular nositlon of the piston $2 since the movement of the piston brings different parts of the tapered groove 3l adjacent the lower edge of the chamber wall Be. In other 'words the piston

hub 121' with its tapered groove 3| and passages 32, 22 and 33 and the said lower portion of the adjacent wall surface 9* serve as a. valve which diminishes the effective capacity of the _outlet conduit of the chamber B as the piston I2 moves downward, as viewed in Fig. 11. The object of this, as will presently more fully appear, is to gradually increase the resistance offered by the device to the compression of the vehicle springs. From the foregoing it will be seen that the two main pressure chambers A and B are joined by two conduits, namely, that formed by par:– sages 23, 22 and ZA and that formed by groove 3| and passages 32, 22 and 33, said conduits constituting parallel connections bctwcen the chambers A and B. While the thermostatic valve stem 21 is subject to the hydraulic pressure, this pressure is always that on the discharge or low pressure side of the throttle valves of the piston I2. Consequently the stem 21 could be made, if need be, of some material liable to deformation under heavy pressure, because the construction above described wholly obviates such heavy ,pressure on the stem 21. Furthermore, the construction of the valve 26– and its relation to the conduit controlled by it, are such that the valve In operation ls substantially balanced with respect to the fluid pressure in said conduit on the inlet side of the valve. In other words, the thermostatic element or part of the valve is not in any way subjected to heavy pressures or stresses and the conditions, therefore, favor its reliable operation. The fact that the hore 22, at both sides of valve 25, is always in free communication with a low pressure chamber of the instrument has another important advantage, namely, that liquid under pressure, leaking through the bearing of shaft extension |33 cannot accumulate and build up a pressure that would force the vane I2 against front plate ID and cause objectionable wear. At thetop of the pressure chamber A (Figs. 11 and 12) is an air bleeding passage 35 of small T0 T5 4 2,oo9,e7e ` bore which leads from the chamber A to the reservoir chamber C. This passage is controlled by a gravity check valve SG in a manner which will later be described. At the bottom of the pressure chamber B is a small passage 31 which leads from said chamber to the reservoir chamber C and which is controlled by a gravity check valve In the manufacture of the shock absorber I prefer to drill the holes in the intermediate casing part 9 and in the front part IU for the cap screws ll, Il about nl," larger in diameter than the cap screws so that a small amount of float is possible between the three main elements of the casing. I determine and hold the alignment of these three casing elements by means of the dowels ||*, the holes for which in the three elements are located in the machining process in the following manner. In the rear plate 8 the holes for the cap screws | | are drilled and tapped and the holes for the dowels ||“, as well as the bore designed to receive the bushing 8_lt;=, are machined in the same jig, the holes for the dowels being drilled JI" under size. After the bushing has been pressed into place the inside bore of this bushing and the dowel holes are simultaneously bored to exact size in a three spindle machine which will give the exactly correct spacing and diameter of these bores. Similarly the intermediate casing part 9 is Hrst drilled with the holes for the cap screws I I about 515' over–size and the holes for the dowels ll* about al,” under size, these holes being located from the inner finished surface 9° of the sector–shape wall of the casing member, said surface 9° and also the surface 9* having been machined by a broaching operation. 'I`he dowel holes are then bored to exact size and at the same time the surface 5° may, if desired, be additionally ilnish bored to correct for possible breaching errors. In the latter case the boring is done in a three spindle boring machine, while if only the dowel holes are bored a two spindle machine is used. In either case the part 9 is located in the jig from the surfaces Sb, Sb, thus insuring exact relative location of the dowel holes and the surfaces 8' and lb. The front part ||I of the casing can he machined in exactly the same manner as the back plate 8 or the following alternative procedure may be used. First the cap screw holes are drilled gh" over size, then the dowel holesare drilled J," under size, then the dowel holes are llnlsh bored and simultaneously the bearing boss IU* is bored, all of these operations being performed in the same jig. The part Ill may then be hardened, preferably by a nitriding process. and finally the bushing ll” is pressed into place and burnished. With either procedure the shaft bearing of the plate IU ls located by a boring operation in the bearing boss and with either procedure the result is that upon the assembly of the three parts the dowels will hold these in such position that the bores of the two bushings and the axis of the surfaces 8” and 9* will be in exact alignment. The plate IU is hardened, as above stated, to prevent objectionable wear of the contacting surfaces oi' said plate and the piston I2 incident to the pressure of the spring 2|. As has been stated, a link 1 serves to connect the crank 5 of the device with the axle 2 of the vehicle. The joints at the two ends of the link 1 are of novel construction and will now be described. The crank arm 5 ls bent laterally and ls formed with a spherical end 6* and the enlarged upper end of the link 1 is formed with an axial bore 1* to receive the bearing for the spherical end 61– of the crank, the side wall of the chambered part of the link being apertured at 1° to receive the laterally bent end of the crank arm. The bearing for the spherical end E' comprises a lower block 35 and an upper block both ot which are cupped to fat the spherical end G“ of the crank. ' Upon the plane top of the upper bearing block 40 rest four sector–shape blocks 4|, 4| which are formed at their top sides with conical surfaces of low pitch and have at their inner comets upstanding lugs 4|*, 4|‘. The under sides of the blocks 4| are recessed to accommodate a radially compresslble and expandible spring such as the spiral spring 42, the expansion of which tends to press these blocks 4| radially apart. Such radial movement of the blocks is prevented by the conlcal under surface of the screw plug 43 which engages the upper threaded end of the link and is locked in adjusted position by means of a snap ring 44 the lnturned end of which extends through an aperture Lu the side of the link 1 to engage any one of a circumferential series of sockets 45, 45 in the screw plug 43, The screw plug is preferably supplied with a lubricant Htting 45 through which oil or grease may be introduced to the bearing, it being understood that the side aperture 1° may be closed with a suitable boot or cover (not shown) in a manner that is well`known. It will be observed that the under side of the screw plug 4| is formed with a conical surface which flts the upper conical surfaces of the blocks II. The pitch of the conical surfaces is such that while the force of expansion of the spring 42 is sufficient to press the blocks 4| radially apart and thus press the upper bearing block 40 toward the lower bearing block 33 to compensate for the wear in the bearing, reverse or radially inward movement of the blocks cannot be caused by the forces to which the bearings are subjected. In other words the adjusting device is :non–overhauling. In the manufacture of the coupling just described, the blocks 4| are readily made from rolled steel bars of sector–shape cross section by assembling four such bars to form a round rod and machining them simultaneously in an automatic screw machine. In assembling–the coupling one end of a. short section of thin tubing (not shown) is passed over the lugs 4|' of the blocks 4| so as to hold the blocks together, the expansion spring 42 ls then inserted between the blocks and the latter inserted through the end of the link into position upon the bearing block 40. The screw plug 43 without the

lubricant nipple 46 is then screwed into position, the assembling tube referred to projecting through the threaded aperture of the block 43 in which the lubricant nipple 46 is later mounted. When the screw plug 43 has been screwed down into contact with the tops of the blocks 4l, the assembling tube referred to can be withdrawn, thus freeing the blocks 4| for outward movement by a spring 42 insofar as such movement is permitted by the plug 43. The lower end of the link 1 is connected to the axle 2 by means ot a bracket 41 which is detachably bolted in a well known manner to thc axle. The bracket 41 is formed with a spherical end HH. which is engaged by a bearing in the end of the link 1 differing somewhat in construction from that in the upper end of the link. The lower enlarged end of the link is bored out axially to receive anupper bearing block 48 and 9. lower bearing block 49 both of which are cupped to flt –_ s,oo9,evs‘ the spherical end 41=, the side wall of the link being formed with a lateral aperture 1° to receive the spherical end of the bracket 41. The lower bearing block 49 is threaded to iii: the correspondingly threaded axial bore of the link and is autoe matically adjusted toward the upper bearing block 48 to compensate for wear by means of s. helical spring 50, the upper end of which is anchored in the bearing block 45 while the lower end is anchored in a screw plug 50° which is adjustably secured in *he threaded bore of the link by means of 2. cotter pin 5\l‘=, When the parts are assembled the helical spring 50 is placed under tension so that it constantly tends to turn the bearing block 45 in the threaded bore in a. direction to adjust said block toward the block 43. In this way there is provided an automatic take~up to compensate for wear, and this can be accomplished by the use of the light spring because the low pitch of the screw threads of the bearing block 49 renders the device non–overhauling. On reference to Fig. 1 it will be observed that with the piston I2 in its normal or intermediate position corresponding to the normal load of the vehicle with the latter standing still or moving over a smooth and even surface, the crank arm 6 is in an approximately horizontal position and at an angle only slightly under 90° with the link 1, while when the vehicle spring 3 is fully compressed the crank 6 (as shown by dotted lines) has turned to a position approaching the vertical and is at a very acute angle with the link 1. In the use of my shock absorbers each vehicle is preferably fitted in the usual manner with a set of four of the devices, one to control the action of each of the four springs. In describing the operation of .the shock absorber shown in Figs. 1 to l'1 andfabove described, it is to be observed at the outset that while the apparatus can be designed as to size and proportions of parts, etc. to meet widely varying conditions of service, it is_especia1ly applicable to and is preferably designed for operation upon a cycle having the principal features of the cycle disclosed in my U. S. Reissue No. 17,409 previously referred to. That is to say, the apparatus is preferably designed to cooperate with vehicle springs that are softer or more iiexible than springs heretofore employed with other types of shock absorbers, the construction of the apparatus being such that it offers a resistance to the iirst part of the compression of the vehicle springs which is small and preferably so slight as to be practically negligible, i. e, unnoticeable to a rider in the vehicle, while after such initial compression of the springs occurs the resistance to further compression afforded by the shock absorber increases relatively rapidly as such compression occurs so that a large resistance is developed to supplement the resistance of the vehicle springs, the maximum resistance being reached at or near the end of the spring–compressing movement of the parts. On the other hand the resistance afforded by the apparatus to the rebound of the compressed vehicle springs is preferably never equal to the maximum resistance opposed to the compression of the springs but nevertheless attains a value at or near the normal position oigthe parts on their movement during rebound which is substantially greater than the resistance otiered to the hrst part of the spring–compressing –movement, The shock absorber is made ready for use by iilling its working chambers with a suitable liquid such for example as a 95 per cent solution of glycerin in alcohol. 'I'he filing may be accomplished by removing the screw closure H* of the casing and pouring the liquid into the reservoir chamber C, meanwhile swinging the piston from its lowermost position to its highest position and if necessary repeating this movement several times until it is certain that suflicient liquid is drawn from the reservoir C through the passage 31 ,into the lower chamber'B and from it forced into the upper chamber A so that both chambers B and A are completely nlled with liquid. It will be understood that when the piston I2 is swung from its lower to its upper position the chamber B is Hlled with liquid While air in the chamber A is forced out through the passage 35 into the reservoir chamber C and thence outward through the filling aperture, while on thc downward movement of the piston I2 the liquid in the chamber B istransferred through the passages in the piston to the chamber A. By repeating the movement oi thc piston it is insured that the chambers A and B are completely filled with liquid, and this having been done, the reservoir C may also be nearly dlled with the liquid to provide a. reserve supply. With the shock absorber mounted on the vehicle and the parts of the apparatus in their relative positions shown in the drawings, if the vehicle wheel strikes an obstruction the axle 2 is lifted, the spring 3 is correspondingly compressed and at the same time the crank arm 6 of the shock absorber is swung toward its dotted line position shown in Fig. I while the piston I2 is swung downward from its normal position as shown in Fig. 1 and Fig. 11. At the beginning of the downward movement of the piston I2 the liquid in th–e chamber B offers little resistance to the movement of the piston because the capacity of the valve groove 3| is great enough to permit a relatively frw outiiow of the liquid from the chamber B through said groove, passage 32, passage 22 and passage 33 into the upper chamber A, the check valve 34 opening to permit such movement of the liquid. However after the downward movement of the piston Q2 has continued for a certain distance corresponding to a. certain compression of the vehicle _spring 3 the more rapidly tapering form of the valve groove 3| causes a greater and greater throttling of the liquid flowing from the pressure chamber B so that energy is absorbed or dissipated in this way at an increasing rate as the piston continues its movement and correspondingly increased resistance to the compression of the spring ls afforded by the shock absorber. 'I'he resistance developed by the shock absorber will of course vary with the size of the obstruction and the velocity with which the vehicle strikes lt. I prefer to design the parts and clearances of the shock absorber so that it will offer suilicient resistance to the compression of the spring 3 to enable it and said spring to fully absorb all shocks that will ordinarily be encountered by the driver of average care and rely upon the rubber bumper 3* to supplement the shock absorber and spring in the case of the rarely encountered extremely heavy shock. I am thus enabled to make the shock absorber parts smaller and lighter than would be feasible if the rubber bumpers were notrelied upon as stated, and this is a consideration of considerable importance when the shock absorber works upon the cycle patented in my said Reissue No. 1'l,409_ Huw.. ever, it is to be understoodthat the groove 1| can be restricted to such a degree as to enable the shock absorber to carry out the functions of the rubber bumper, rendering the latter

l1l111€¢– essary. While the weight of the parts of the shock absorber and the closeness of nts must be increased if this is done, a distinct improvement in the riding quality of the vehicleis secured thereby because the shock absorber, unlike the rubber bumper, ceases to exert a separating force between the axle and the frame the moment these parts cease to .approach each other, with the result that the energy and rebound tendency imparted to the frame is less than when the rubber bumper is used. For those cars ,for which the best obtainable riding quality is more important than cost it will be desirable to eliminate the rubber bumper and have the shock absorber perform its function. When the upward movement of the axle 2 ln relation to the frame l ls arrested the spring l tends to return to its normal loaded form and this so–called “rebound” of the spring starts to swing the crank arm 5 downward and the piston l2 upward. This movement of the piston places the liquid in the chamber A under pressure and forces it through_ the piston passage 13, past the thermostatic valve part 26° into the passage 22 and thence through the passage 2| and past the check valve 2| into the pressure chamber B. The positioning of the tbermostatlc valve 25 ls such that a sulllclent resistance is offered to the outflow of the liquid from the chamber A into the chamber B to adequately check the rebound of the springs. When relatively soft and flexible suspension springs are employed and the shock absorber is designed, as preferred, to adequately supplement the resistance of the springs to compression when obstructions are encountered the force of this resistance afforded by the shock absorber is relatively large at its maximum and the resisting force atforded by the shock absorber to the rebound of the spring would never exceed the said maximum resistance to the compression of the spring and ordinarily would at all times be less than said maximum resistance, while it should materially exceed the minimum resistance afforded to the compression of the Springs at the time the parts are at or near their normal position in the rebound movement. I prefer to make the resistance to the rebound of the springs at the time the shock absorber parts are at or near their normal position in the rebound movement' of a substantial amount in excess of the minimum of resistance afforded to the compression of the springs, as Just stated, because the shock absorbers in this manner add Sreatly to the lateral stability of the vehicle. or in other words greatly resist the tendency of the body of the vehicle to rock or SWE? laterally while it ls paslng over surfaces that may be smooth yet sutllciently undulating to cause such rocking or swaying. This feature of the apparatus is of especial importance when the shock absorbers are designed to operate upon the cycle patented ln my aforesaid Reissue No. 17,409 since with that cycle of operation the resistance of' the shook absorbers to the com.– llresslon of the springs when the parts are at or near their normal positions must be so small as to be practically unnotlceable in order that the advantage of the sott vehicle springs may be had, and consequently the said resistance to the compression of the springs is not sutllcient to adord the lateral stability referred to and lt ls only by making' the resistance to the rebound force of the springs amply large when the parts _ a,ooo,s7e t ' are at or near their normal positions that the said lateral stability is attained. The character of the forces set up in the pressure chambers A and B of the preferred form of the device is illustrated by the diagram shown In Fig. 3. In this diagram the forces are measured vertically above and below the horizontal line or axis 1:–as. The vertical line 11–11 represents the normal position of the shock absorber piston l2 and movement of the piston in either direction from that normal position is measured horizontally on the axis l–1:. In the diagram the full line curve a and the dotted line curve Z1 represent two complete cycles of the piston movement such as occur when the wheels of the vehicle strike an upwardly projecting obstruction, the curve a corresponding to a larger obstruction than the curve b or to an obstruction encountered at greater speed than that represented by the curve b. Considering the full line curve a. it will be observed that when the obstruction was encountered there was a considerable downward movement ol’ the piston l2 during which there was very slight resisting pressure set up in the chamber B, this pressure being represented by the practically horizontal section al of the curve a to the right oi' the vertical line y–y. However, as the downward movement of the piston l2 continued, the rapidly tapering end portion of the valve groove 3| caused a rapid increase of the pressure in the chamber B which is represented by the sharply upwardly inclined portion zz’ of the curve. The pressure reaches its maximum value at the point al near the end of the downward movement of the piston l2 and then, as the speed of the piston movement rapidly dimlnishes, the pressure in the chamber B correspondingly rapidly falls as indicated by the portion a* of the curve, the pressure falling to zero of course at approximately the end of the piston movement. At this point the rebound movement of the spring l begins, causing a reversal of the movement of the piston l1 and the relatively rapid building up of pressure in the chamber A which is represented by the portion af' of the curve. The pressure in the chamber A measures the resistance to the rebound of the spring and after reaching a maximum continues at or slightly below that maximum value for a portion of the rebound movement and then falls off as the vehicle and shock absorber Darts approach their normal positions represented by the vertical line y–y. 'I‘he momentum of the parts moved by the rebound or expansion of the springs carries said parts beyond their normal positions and the pressure in the chamber A continues but with diminished intensity as indicated by the section as of the curve to the left of the line 14–11, the pressure retumlng to zero at or near the end of the rebound movement. From this latter point the parts are retumed again to normal position, the piston l2 moving downward and creating the very slight pressure in the chamber B represented by the section al of the curve. The dotted line curve bln the diagram, Fig. 8, represents the pressures set up in the chambers A and B when the vehicle encounters a lesser shock or obstruction than that represented by the curve a, the curve being of the same general character as the curve u but indicating the lesser pressures generated. While the curve illustrating the cycle of force variations will vary in form with the speed of the vehicle and the contour ot the road, curves a. and b represent usual forms. The size and taper of the valve groove 3| in the hub of the piston l2 are preferably determined empirically `to satisfy the conditions of operation determined by the size and weight of the vehicle upon which the shock absorber is to be used, However the effect of the valve groove 3| can be varied quite materially by angularly adjusting the piston l2 in relation to the crank arm 6, this being accomplished by angular adjustment of the crank on the piston shaft which is permitted by the toothed or serrated surfaces of these parts. By such adjustment of the shock absorber piston in relation to its crank arm the device can readily be adaptedjto the dilferent weights of the open and closed types of bodies of a car model of a given wheel base. To facili1 tate the positioning and adjusting of the crank on the piston shaft reference marks may be placed on the adjacent surfaces of these parts where they are engaged by the washer lS. In Fig. 11 the full and broken lines represent three of the different positions to which the piston l2 can be angularly adjusted for a given angular position of the crank 6. Similarly the position of the valve 2E is

empirically determined in order that it may afford the desired resistance to the rebound of the springs, the position of the valve, as previously described, being determined by the adjustment of the abutment plug or screw 28. When once this adjustment has been determined for a given vehicle the resistance is automatically main~ tained at a nearly constant value, regardless of temperature changes, by reason of the diiferential expansion of the valve stem 21 in relation to the metal parts of the piston and its shaft. It will be apparent that a relation exists between the perimeter and width of opening of the valve part 26° and the ditferential expansion of the valve stem 21 and the metal piston and shaft structure, so that the diameter of the bore 22 in the piston, which in turn determines the effective diameter of the valve 26, will be determined by the said diiferential expansion, which in turn is determined by the length of the stem 21 and the respective coenicients of expansion of the stem and of the said metal structure, In the operation of the shock absorber when the piston I2 starts its upward movement the pressure in the chamber A causes nuid in the chamber to enter the air bleeding passage 35. If any air has found its way into the chamber A it first passes the ball valve 36 and then as soon as liquid enters the passage 35 the ball valve is lifted by the flowing liquid against the seat above the valve thus effectively closing the passage as long as pressure ls maintained in the chamber A. If during this upward movement of the piston I2 liquid ls not delivered from the chamber A into the chamber B rapidly enough to keep the latter chamber nlled a corresponding lowering of the pressure in the chamber B would result and thereupon liquid from the reservoir C will be drawn past the check valve 38 through the passage 31 into the chamber B to make up the deficiency, therein. When the piston I2 moves downward the valve 33, of course, remains upon its seat and keeps the passage 31 closed. Wliile any air present in the reservoir chamber C naturally collects at the top of said chamber the churning of the liquid in said chamber may cause absorption or occlusion of slight amounts of the air in the liquid therein so that slight amounts of air may pass through the passage 31 into the lower chamber B, but any small amount of air thus entering the chamber B promptly tlnds its way in the operation of the apparatus through the piston passages into the upper chamber A whence it is discharged in the manner previously described through the bleeding passage 35'back into the reservoir chamber C. _ It will be observed that in the operation of the shock absorber any slight leakage of liquid that may occur from the pressure' chambers A and B is received by the reservoir chamber C from which the supply of liquid in the chambers B and A is constantly replenished. Any leakage of liquid from the reservoir chamber C must occur between the iiange I9 of the casing member I1 and the adjacent face of the crank arm G, and such leakage is practically completely prevented by the packing 20. This packing, I believe, has novel and advantageous characteristics. The spring 2| pressesthe packing as an entirety outward against the inner face of the crank arm G. This has the effect of pressing both the metal ilange 20“' and the outer side of the soft ring 20" against the said face of the crank arm; and it has the further effect of expanding the soft rings 20° and 20° laterally against the inner wall of the casing flange I9 as well as against the outer wall of the metal ring 209. The eEect is to form liquid tight joints between the rings 20” and 20° on the one hand and the ilange I9 and the ring 202 on the other hand and the friction between these parts is greater than that between the packing 20 and the face of the crank 6 so that the packing ring is held against turning and a sliding contact is maintained between the packing 20 and the crank E when the latter turns. In this connection it may be observed that the metal ring 20d tends to reduce the angular movement or distortion of the packing under reversals of the crank movement. At the beginning of the service of the device reliance can be placed upon the soft packing ring 20” of rubber or the like to maintain the joint between the packing 20 and the crank 6 tight and by the time wear of the packing 20” has occurred the metal flange 20= and the face of the crank 6 engaged by it will have worn in to form a good liquid tight metalto–metal joint, and this joint is indelinitely maintained in the operation of the apparatus, It will readily be appreciated that in a. shock absorber operating upon the cycle which characterizes my previously mentioned Reissue No. 11409, which operates in conjunction with very soft or flexible vehicle springs and which must therefore afford correspondingly high resistances to the compression of the springs, the forces transmitted by the connection between the vehicleaxle and the hydraulic parts of the apparatus attached to the chassis frame and the axle structure are of considerable magnitude in both directions, Consequently it is essential that the joints connecting the link 1 to the crank arm 6 and to the axle bracket 41 should not only be amply strong but susceptible of adjustment for wear. These conditions are well met by the link joints at the upper and lower ends of the link. Notwithstanding the heavy forces transmitted by the link the very light spring 42 (or 50) serves to maintain the ball end of the link and its bearing blocks in operative contact because of the* non–overhauling character of the takeup, and the use of such a light spring insures light bearing pressures except when heavy stresses are being transmitted through the coupling and this correspondingly diminishes wear of the bearing. Obviously the c.nstruction also affords a free or fl 8 V 9,009,516 ‘ A universal movement characteristic of the ball and socket joint so that there can be no binding in the joints. I have already pointed out the changing angular relation between the link 1 and the crank 6, the angle increasing from nearly right angles when the parts are in their normal/position as shown in full lines in Fig. 1 to a relatively small acute angle when the spring 3 is fully compressed. On reference to Fig, 1 it will be observed that the wide variation of this angular relationship is made possible by the fact that the axis of the piston shaft is relatively close to the front side of the shock absorber casing so that when the link 1 has 'been swung backward to the dotted line position shown in Fig. 1 it ls relatively close to the said axis and makes the relatively small angle with the crank 6 which was referred to. Since it is highly desirable to avoid the use of overhung bearings, this latter feature is one of considerable practical importance in hydraulic shock absorbers which must afford the high resistances to spring compression necessary where very soft or flexible springs are employed, the significance of the arrangement being that as the pressure in the chamber B rapidly increases (as shown by the section 112 of the curve a in Fig. 3) to its high maximum value the mechanical advantage with which the spring compressing force is applied from the axle 2 of the vehicle to the piston I1 of the shock absorber is simultaneously diminished by the change of the angular relation between the link 'I and the crank 6 so that the size and strength cf the liquid pressure parts of the shock absorber apparatus can be made substantially smaller than would be feasible if the said mechanical advantage were not changed as described, and still be adequately strong to perform their functions. It is to be observed that the fundamental principle here involved is embodied in the shock absorber construction disclosed in my previously mentioned Reissue No. 17,409 in which construction a reciprocating type of. piston is employed. In the present construction I am enabled to utilize the same principle by adopting a single oscillating vane type of construction which permits the use of an

eccentric casing with the axis .of the piston shaft near one side of the casing. _This type of ,construction has a very distinct additional advantage in 9. shock absorber designed to resist the compressive force of a soft vehicle spring. That is to say, the single vane form of construction is peculiarly adapted to furnish thewery great resistance capacity necessary for such service since with it the necessary capacity can be secured with a casing structure smaller, more compact, lighter in weight and less costly than is possible where a. multiple vane construction is used, because the capacity of a vane type piston varies as the square of its mean effective radius and my studies have shown that because of this principle a distinctly higher degree ot compactness can be obtained for high capacity shock absorbers by the use oi' the, single vane piston. The method of machlnlng the peripheral walls of the sector–shape chamber of the main casing of the shock absorber is highly advantageous because of its relatively low cost. This method is made possible, without sacrifice of desired accuracy, by the three–part construction of the main casing and by the novel method of machining the dowel holes ..nd piston shaft bearings by locating them with reference to the breached surfaces. By combining with these features the outer welded–on casing member I1, I provide a reserve reservoir of large capacity, obviate the necessity of making the joints between the three casing parts 5, 9 and IU absolutely liquid tight and secure a structure with a. smooth and highly pleasing exterior. _ The provlslcn`of a piston construction that Includes all passages, ports and valves controlling the flow of liquid between the two main pressure chambers combines many of the machining operations in this single part of the apparatus and thereby facilitates manufacture. Other advantages Incident to the construction above described and more or less common to the other forms of construction yet to be described will be pointed out below more fully. Referring now in detail to the form of appara–_ tus shuwnvin Figs. 18 to 28 inciusive, 5l is the channel side bar of an automobile chassis frame, 52 ls the front axle of the automobile and 53 is one of the semi~elliptical springs upon which the chassis frame is suspended In the usual manner from the front axle. 53° is 9. rubber bumper secured to the upper side of the spring 53 so as to engage the under side of the frame channel 5| when the spring 53 is fully compressed. 54 designates as an entirety the main body or casing part of the modified form of shock absorber, said casing being rigidly secured to the frame channel 5| by bolts 55, 55. 5| is the operating crank arm of the shock absorber and 51 is a link by which the crank arm is connected to the axle 52. In Figs. 19, 23, 24, 25 and 26 is shown the con– –struction of the main or body part of the shock absorber. There ls a casing structure which comprises a rear plate–like part 55, an intermediate part 55 and a front plate–like part GU. Preferably the part 58 is a steel forging and the parts 59 and GB are iron castings. As in the first form of,construction, the 'parallel side surfaces of the intermediate casing part 59 nicely fit the adlacent plane surfaces of the rear and front parts 58 and SU, and the three parts are tightly and rigidly secured together by through bolts 6| and Gil, The larger bolts Sl* suitably flt the apertures in the parts 55, 5! and 60 to serve as dowels. The intermediate casing part 58 is formed with lugs 5B', 58° to receive the securing bolts 55, 55 previously referred to. Additional parts and features of the casing structure will later be described. As indicated in Fig. 24, the intermediate casing Dart 59 forms the peripheral wall of an approximately sector–shape chamber. In this chamber is fitted a. piston 51 of the vane or swinging type. said piston comprising a vane part 52' having a web and flange construction as clearly shown in Figs. 23 and 24, and a cylindrical hub part 62° which carries the vane. The said hub part of the piston ls rigidly and preferabfy integrally connected as shown to a. shaft 63 which extends through the front casing member 5| and which ls smaller in diameter than the piston huh and is rotatably supported in a bearing boss CI' of the casing member, said bum being Iltted with a suitable bushing 55", The peripheral wall of the sectorslzape chamber of the casing ls formed with a hollow cylindrical extension at ll* to accommodate the hub part II” ot the piston (Fig. 24). The chamber wall at ill and at Sl", the inner plane surfaces of the casing parts 5| and 81| and the various surfaces of the piston which are adjacent to and cooperate with these casing surfaces are all machined or tlnlshed fn afford working nts between the piston and the walls of the casing member that will prevent undue leakage of the T0 T5 working fluid from one side of the piston to the other. To provide a. reserve reservoir for working fluid, the front casing member GU is formed on its outer side with a chambered extension 60” of a sectorshape corresponding approximately to the shape of the main chamber of the casing, the reservoir chamber being connected, in a manner which will later be explained, to the main chamber of the casing. The crank arm 56 of the device ls mounted on the outer projecting end ot' the shaft 83, the shaft and the aperture of the crank arm being toothed or serrated at G4 so that the crank can be placed on the shaft and rigidly held against turning in diiierent angular positions in relation to the shaft and the piston 62. The crank is secured agalnst axial movement on the shaft by a closed nut 55 which engages the threaded end of the shaft and an interposed washer $6 of soft metal or other ,suitable material is interposed between the nut and the outer face of the crank arm so as to tightly seal the joint between the crank arm and the shaft. An annular packing 61 surrounds the outer end of the bearing boss GBR of the casing and is interposed between the inner plane face of the crank arm ‘JE and the oppositely disposed parallel surface afforded by the outer side of the reservoir SU” and a shoulder–like extension 6 ° of the bearing boss We (Fig. 23). The annular packing E1 comprises a ring S1“ of soft (or deformable) and resilient liquid tight or liquid repellant materal, such as rubber, and a. metal ring 61” which surrounds the 1 ing 61” and is formed with an inwardly turned flange 61\=', the outer face oi' the said flange S1°' and a. portion of the outer face of the soft ring 51” being arranged to engage the adjacent inner face of the crank 5E while the inner side of the ring 51” alone engages the oppositely facing surface of the casing structure. The dimensions of the soft ring E1“ are such that said ring is placed under pressure arid deformed when the parts are assembled with the result that the surfaces of said ring are tightly pressed against all of the surfaces with which the ring contacts and at the same time the flange B1‘_gt;' of the metal ring 61” is yieldingly pressed against the inner face of the crank SE. With this construction an effective seal is provided preventing any material leakage of liquid around the shaft 63 and between the casing and the crank 56. ‘ As indicated in Fig. 24, the piston 62 divides the sector–shape cavity of the casing structure into a chamber A’ above the piston and a chamber B' below the piston; and as is shown in Figs. 23 and the reservoir extension 60° provides a reservoir chamber C’. In the operation of the device the chambers A’ and B' and the chamber or reservoir C’ are occupied by a body oi' liquid which constitutes the working Huld of the device, glycerin or oil of suitable consistency being preferably employed. The reservoir 60” is provided at its upper side with a fllling aperture and with a. suitable screw closure 65 to provide for thelntroduction of the liquid. In the operation of the device the chamber/ A' constitutes a pressure chamber for resisting the upward movement of the piston G2 and thus checking rebound of the vehicle springs

while the chamber B' serves as 9. pressure chamber 'to resist the downward move~ ment of the piston SZ to check and control the compression of the vehicle springs. I shall now describe the features of construction which provide for the carrying out of these functions. As shown in Figs. 23, 24 and 25 the hub of the piston is formed with a large axial bore 69 comprising a screw threaded section 59° of' large diameter and a section 691' of smaller diameter. As shown in Figs. 24 and 25 the inner face of the casing member EB is formed with a groove TU which forms a passage connecting the chamber A' with the inner end of the bore 69 of the piston hub. 1| is a radial passage (Fig. 24) formed in the hub of the piston and affording communication between the smaller diameter section 69” of the bore 69 and the pressure chamber B', said passage 1| being controlled by a. check valve 12 which permits Row only in a radially outward direction through the passage. The conduit formed by the passages 10, 69 and 1| is controlled by an automatically operating thermostatir Valve 13 which is disposed in the larger section 69° of the bore G9 and is connected to an elongated stem 13' formed of material having a coeflicient of thermal expansion differing very substantially from that of the metal of Which the piston 62 and shaft 63 are formed. I find ebonlte a suitable material for the valve stem 13' and prefer to form the valve 13 and the stem 13' integrally from this material. The shaft B3 is drilled out as shown to accommodate the elongated valve stem 13’. In the enlarged section GSB of the bore 69 ls mounted an apertured valve seat 14 which has a threaded periphery to engage the internal threads ofthe bore 69 so that the valve seat. can be adjusted toward and from the valve 13. A coll spring 15 interposed between the casing member 58 and the valve 13 presses said valve yieldingly away from the seat 14 and maintains the outer end of the valve stem 13' in engagement with the abutment formed by the closed end of the bore of the shaft which accommodates said stem. –It will be seen that by adjustment of the valve seat 1l the valve 13 may be made to afford a nice control of the now of liquid from the pressure chamber A’ through the passages 10, 69 and 1| to the chamber B', and this control automatically substantially compensates for temperature variations because of the differential expansion of the valve stem 13' and the metal of the piston E2 and its shaft 63, ebonite having a substantially greater coemclent of expansion than the metal. The valve seat can be secured in adjusted position in any suitable manner, as by upsetting the screw threads with a suitable tool or by giving the seat a sufficiently tight an in the threaded bore. g As shown in Figs. 23 and 24 the hub 62° of the piston is formed with a radial passage 15 which communicates at its inner end with the bore and at its outer end is arranged to communicate with a tapered groove 11 formed in the surface 59° of the casing. In line with the passage 16 is a passage 18 in the piston hub, said passage being controlled by a check valve 19 which permits flow through said passage only in a radially outward direction. The groove 11, the passage 16 and the passage 18 constitute a. conduit affording communlcatlon between the pressure chamber B’ and the chamber A' and lt will be observed that the capacity of this conduit is automatically varlecl as the piston moves as by such movement the outer end of the passage 16 is brought into communication with dillerent parts of the tapered groove 11, the capacity of the conduit heing diminished as the piston G2 moves downward during the compression of the vehicle spring. Consequently the el1'ect of the taper of the groove 11 is to gradually increase the resistance ' p 2,009,676 ` offered by the device to the compression of the vehicle springs. In this second form of the apparatus, just as in the trst form, there are” two conduits forming parallel connections between the two main pressure chambers, the one conduit being formed by passages 10, G! and 'll and the other conduit by groove 11, and passages 16 and 18. ' At the top oi the pressure chamber A’ (Figs. 19 and 25) is an air bleeding passage 88 which adords communication between the top of the chamber A' and the reservoir chamber C’, said passage being controlled by a valve BN in a manner which will later be explained. At the bottom of the pressure chamber B’ is a small passage ll (Figs. 19 and 26) which affords communication between the reservoir chamber C' and the pressure chamber B’ and which is controlled by a check valve 82 which is subject to a very light spring pressure. While it is possible to machine or finish the meeting surfaces of the casing parts 58, 59 and S0 so that leakage of liquid from the pressure chambers A’ and B' is thereby practically completely prevented, I prefer to provide additional assurance in this regard. To this end the lateral surfaces of the intermediate casingpart 59 are provided with shallow grooves 59C and 595 which extend entirely around the sector–shape chamber ol' the casing inside of the secxu–ing bolts lil. These shallow grooves can be pressed in the faces of the casing member 59. The groove 59° is connected by a passage 59° (Fig. 23) with the groove 59° and the latter groove ln turn is connected by 9. passage Glld with the reservoir chamber C'. It will thus be seen that any liquid Ending its way lromthe sector–shape chamber of the shock absorber between the meeting faces of the casing sections will enter the grooves 59° and 59° and as any liquid thus entering these grooves cannot be under pressure it will readily drain into the reservoir chamber C'. The joints at the two ends of the link 51 which operatively connects the crank 56 to the axle 52 of the vehicle are ot novel construction. The crank arm 58 is bent laterally as shown in Fig. 23, to avoid overhanging of its supporting bearing, and is formed with a. spherical cupped end Elin while the link 51, which is preferably formed with a channel section to secure the combination of lightness and strength, has its upper end ccrrespondingly formed with 9, spherical cupped section 51°. 'I‘he parts Eif* and 51” are apertured as shown in Fig. 23 to receive a coupling pin 83, said pin fitting the aperture in the part 51" while the larger aperture formed in the part 56“ affords a considerable clearance between the latter part and the pin. The pin B3 has a head 83° the lnner side of which has a spherical form to lit the adjacent abutting spherical surface of the part 551. On the smaller end of the pin B3 is a disk 84 which ls recessed on its outer face to receive a locking pin 85 which extends transversely through the pin 83. Between the disk B4 and the adjacent convex surface of the part 51° of the link is a split ring 88 having normally the shape shown in Fig. 28. In assembling the parts the pin I3 can be passed through the crank, link, and disk M and the securing pin 85 placed in position, then the snap ring 86 can be placed upon the sloping surface ll* of the disk 8| and forced over the periphery of said disk, whereupon it snaps into position between said disk and the convex face of the link as shown in Fig. 23. The resiliency of the ring li causes it to contract and thus hold the spherical surfaces of the crank, link and pin B3 in snug contact with each other so that as wear ofthese contacting surfaces occurs the spring ring BS automatically takes up the slack and compensates for the wear. The pin 83 is preferably provided with a lubricant nipple 83° and suitable passages to conduct the lubricant to the contacting spherical surfaces of the connection. The lower end of the link 51 is connected to the axle 52 by means of a bracket 81 which is clamped to the axle 52 in the usual manner and is formed with a concave–convex end which is secured to the lower end of the link 51 by means of a. joint or connection similar to that which connects the upper end of the llnk to the crank, so that the lower connection need

not be further described. Hgs. 18, _19, 23, 24 and 25 represent the parts of the apparatus in their normal positions corresponding to the normal load 01' the vehicle with' the latter standing still or moving over a smooth and even surface and it will be observed that with the piston B2 in its intermediate position the crank 55 is in an approximately horizontal position and at an angle only slightly less than 90° with the link 51, while when the vehicle spring 53 is fully compressed the crank 56 (as shown by the dotted lines in Fig. 18) has turned to a position approaching the vertical and is at a. very acute angle with the link 51. It will be understood that in the use of the second form of shock absorber now being described. just as in the case of the first form ol' construction, the vehicle is preferably fitted in the usual manner with a set of four of the devices, one to control the action of each of the four springs. As in the case of the first form of construction the second form of apparatus, while it can be designed as to size and proportion of parts, etc. to meet the Widely varying conditions of service, it is especially applicable and is preferably designed for operation upon the cycle disclosed in my previously mentioned Reissue Nol 17.409, The shock absorber is prepared for use by introducing a suitable liquid into its working chembers and its reservoir, a 95 per cent solution of glycerin and alcohol being preferred for this purpose. The Hlllng may be accomplished 'oy removing the screw closure E8 01' the casing, pouring the liquid into the reservoir chamber C' and then proceeding substantially as ln the illling of the ilrst form oi shock absorber as above described. _ With the second form of apparatus mounted on the vehicle inthe manner described its operation is substantially the same as that of the tlrst described shock absorber and it is believed that the operation will therefore be readily understood without further description. It will also be obvious that in order to insure that the second form of apparatus will function in the manner illustrated by the diagram of Fig. 3, the size and taperof the groove 11 and the adjustment of the seat 14 of the therxnostatlc valve 1| will be determined empirlcally to suit the character of the car upon which the apparatus is to be used. It will also be understood that as in the first form of construction the edect of the tapered groove 11 can be varied to a certain extent by angular adjustment of the piston 82 ln relation to the crank arm 56, three of the different positions of adjustment of the piston being indicated by the full and dotted lines in Fig. 24. It will be further understood that the mod– 2,ooo,evs 1 1 iiied form of packing 61 employed in the second form of construction functions in a manner equivtlent to that of the packing 20 in the first form of construction, the resilience of the soft ring 61" in the second form of packing being relied upon to keep the packing surfaces in contact with the respective surfaces without the use of supplemental means such as the spring 2| employed in the first form of construction. Except for the formation of the passages 10 and 11 in the casing structure in the second form of the device, the piston construction has the advantage, pointed out in ccuncction with the nrst form oi' construction, that many machining pperations are combined in the one piston part thus greatly facilitating manufacturing operations. In the sceond. form of construction the ball and socket couplings of the link 51, while markedly different structurally from the link couplings of thc first construction, yet embody the same principle that the spherical surfaces of the coupling are maintained in working contact, regardless of wear, by a relatively light spring which is rendered effective by the non–overhauling feature of the wedging action ,which the spring 86 has between the adjacent surfaces of the parts 51s and Bd. In the case of the second form of ccnstruction. and for that matter in the ease of the nrst form of construction also, the empirical adjustment of the thermostatic valve may be eiTected in a suitable testing fixture in which the piston may be mounted and have its passages subjected to standard hydraulic pressures and adjustmcntof the thermostatic valve or of its scat eiccted to secure a desired eiiect known by test to correspond to the desired operation of the assembled mechanism under actual working conditions. In the third form of construction shown inFigs_ 29 to 35 I have embodied my novel thermostatic rebound control valve and a modliied form of valve for automatically controlling the resistance to the spring compressing forces, in a doubleacting apparatus employing two plunger–type pistons operating in separate cylinders. In this form of construction there is a casing structure BI comprising the main casing part SI" and a cover part 9l1= which is secured to the body of the casing 9|° by cap screws 92, 92, preferably with an interposed gasket 93 to form a, liquid tight joint. The casing structure is formed with two upright cylinders SI" and 9|d. In the cylinder 5|= is a trunk type piston 94 and in the cylinder BI" is a similar piston 95. These pistons may be made by die casting and in such event the heads of the pistons are provided with harcl steel inserts 94a and 955, respectively. The two pistons are yieldingly pressed upward by suitable springs 95, 96 which engage the bottoms of the cylinders and the under sides of the piston heads. The two pistons are formed with small air bleeding ports 94" and S5". respectively. which extend through the side walls of thc pistons adjacent the heads thereof. With the pistons operatively mounted in the casing structure as ,described the interior of the casing is divided into two pressure chambers A" and B" and a reservoir chamber C". The side walls of the casing structure at the upper part thereof are provided with bearings 91 and S8 for the shaft 59 of an actuating crank lG0. The shaft and crank are rigidly and preferably integrally connected together. The bearings 91 and.!|8 are preferably provided with suitable bushings 91° and 9B". Within the reservoir chamber C" of the casing is a piston actuating member l I which is rigidly secured to the shaft 99 by n{ tapered pin |02 and a screw plug |03 by means of which the tapered pin is forced and held in firm engagement with the shaft and the member IDI. The dimensions of the parts are such that when they are assembled as shown in the drawing the faces of the crank |00 and of the member IDI are held in close contact with the adjacent faces of the bearing 91 so that the bearing is rendered practically proof against leakage of liquid. though if desired a packing ring may be interposed between the inner side of the crank arm and the end of the bearing 91. Leakage through the other bearing 98 is prevented by a plate S06 which is forced into the aperture of the bearing with a tight flt. The member 10| is formed with piston–actuating arms IDI" and I0 I U which engage the hardened inserts of the pistons 9| and S5 respectively so that when,the shaft is rocked in one direction the piston 94 is forced downward while the other piston is permitted to rise under the pressure of its spring 96 and when the rock shaft is turned in the opposite direction the piston 95 is forced downward while the piston 9| is permitted to risc under the pressure of its spring The apparatus is designed to have a body of suitable liquid such as oil or the glycerin solution previously referred to, introduced into the pressure chambers A", B" and the reservoir C" so as to 1111 the pressure chambers and at least partially fill the reservoir. To provide for suitably controlled movement of the pistons SI' and 95 the casing structure is provided near the lower part thereof with passages constituting two separate conduits between the pressure chambers A" and B", said conduits forming, so to speak, two parallel means of communication between the two pressure chambers. One of these conduits is formed in part by a valve chamber |05 (Fig. 33) which at one side is connected by a zig–zag passage |08 with

pressure chamber B", while at its other side it is connected by a passage' |01 with' the pressure chamber A", the passage |01 being formed partly in the casing structure proper and partly in a screw plug |03 which closes the lower end of the valve chamber |||5. The passage |06 is provided with a spring pressed check valve Ill! which permits liquid How in one direction only, viz. from the chamber A” to the chamber B”. The passage of liquid through this conduit is further controlled by a valve ||0, the lower peripheral edgc of which cooperates with the adjacent annular upper face of the plug |08 to restrict dow of liquid through the passages |08 and HIS. The valve ilil has an elongated stem HUP* which extends upward in a suitable bore formed. in the casing structure as shown in Fig. 31. the upper end of the bore forming an abutment against which the stem. is pressed by i–he spzing ||I interposed between the valve H0 and the plug l0B. The valve stem ||0= is made of material, such as ebcnite, having a higher coeillcient of thermal expansion than the metal casing structure, and preferably the valve ||0 and its stem IIB" are integrally formed of the same material. It will be observed that a washer H2 is interposed between the ilanged head of the plug |08 and the casing and, by providing washers of different thicknesses. the upper annular face of the plug can be adjusted to diiferent positions relative to the valve H0 by the use of different washers. . ~ The second conduit affording communication between the 'lower ends of the chambers A" and 1 2 _ _ 2.oo9,e'm ~ B" ls formed in part by a valve chamber Ill which is provided by forming the middle part of the main. casing with an upright cylindrical bore extending from the bottom of the casing member to the ruervoir C" at the upper end thereof. Thevconduit in question consists further ofva zig–zag passage Ill extending from the valve chamber H3 to the pressure chamber A", the passage IM being provided with a spring pressed check valve H5 which permits dow only from the valve chamber to the pressure chamber A". The said conduit is completed by the passage IIS which is formed in part in the main casing member BI” and in part in a. screw plug H1 which closes the lower end of the valve chamber I I 3, the said passage H6 affording communication between the latter valve chamber and the pressure chamber B". The second conduit that is provided between the pressure chambers A” and B" has in addition to the cheek valve H5 a further controlling means in the form of a valve Ill which cooperates with a seat ||`|° formed on the upper end of the plug ||1. The valve H8 is provided with a compound thermostatic stem designated as an entirety by IIB and comprising a tubular part Il e which rests upon the valve IIB, a second tubular part I |911 within the part I I 9° and a rod like part ||9° within the tubular part I lib. The part HQ" has its upper end flanged outward to rest upon the upper end of the part HSI* and its inner end flanged inward to support the part |I9=. The parts H91 and I|5° are formed of some material. such for example as ebonlte, having a higher coefdcient of expansion than metal while the part HS” is formed of metal. The upper end of the stem part ||8¢ is fitted with s. hardened metal cap ||9d which is designed to engage with a cam

Abstract:
Source: US2011000496A The present invention provides systems and methods for treating wounds in patients who lack the innate ability to regulate glucose (e.g., diabetic patients). In one aspect of the invention, a method includes positioning an internal bypass device within the duodenum to inhibit contact between chyme passing therethrough and an internal wall of the duodenum and maintaining the internal bypass device within the duodenum for a sufficient period of time to decrease insulin resistance and reduce a blood glucose level in the patient. The internal bypass device increases peripheral blood flow and elevates an immune system response to accelerate healing of the wound.

Abstract:
Source: US2008004657A Described are devices, methods, and systems useful in the treatment of fistulae, and in certain embodiments those having openings extending into the alimentary canal, such as anorectal fistulae. Illustratively, an anorectal fistula can be treated by placing a volumetric construct within the primary opening of the fistula. In certain embodiments, the volumetric construct can include a rolled remodelable material processed to form a substantially unitary body. Advantageous such remodelable materials can include collagenous extracellular matrix materials, such as small intestine submucosa.

Abstract:
Source: US2016030050A Disclosed herein are medical devices comprising a single−lobed, thin−walled, expandable body and a flexible, elongated delivery device for treating saccular vascular aneurysms and occluding segments of blood vessels and other biological conduits. The expandable bodies may include gold and other metals that can be compressed, positioned in the lumen of an aneurysm, or other biological conduit and expanded. The external surface of the expandable bodies can be configured to promote local thrombosis and to promote the growth of tissue into and around the surface in order to reduce migration of the expandable body and to occlude and seal the aneurysm or biological conduit. For the treatment of saccular aneurysms, the expandable body may be deployed in combination with one or more coiled wires that contact both the wall of the aneurysm and the expandable body and exert force on the expandable body to aid in sealing the aneurysm neck.

Abstract:
Source: US2015327717A The brewing system disclosed herein includes a moving inlet nozzle for use in intermixing hot water and coffee in a coffee cartridge. The inlet nozzle may include one or more flow ports that inject hot water into an inner chamber of the coffee cartridge at select angles, locations and pressures to create the desired fluidized mixture of hot water and beverage medium.

Abstract:
Source: US2005096498A A kit and method are described for treating congestive heart failure. The kit may comprise multiple components including a shaping device, deployment tool, patch, and suture. The method may utilize one or more of these components.

Abstract:
Source: US2007060878A An occlusive guidewire system having an ergonomic handheld control mechanism and torqueable kink−resistant guidewire having a distally located inflatable balloon. The present invention provides convenient structure and overall mechanism for operation of a torqueable kink−resistant guidewire, including evacuation and inflation control of an occlusive balloon, and sealing and severing of a crimpable inflation tube which is in communication with an occlusive balloon. The torqueable kink−resistant guidewire includes a centrally located shaft which imparts robustness to the torqueable kink−resistant guidewire. An inflation lumen aligns within the torqueable kink−resistant guidewire for inflation of the balloon.

Abstract:
Source: US2003092667A Therapeutic compositions are delivered to a target site using a catheter which includes at least one ultrasound transducer coupled to an energy source. The therapeutic compositions include genetic material and the target site may be a DNA with affinity for the genetic material.

Abstract:
Source: US2001025155A A multifunctional device for use in an endoscopically performed operative procedure of the type where a narrow portal is established through the skin to provide access to an operative site and the multifunctional device is introduced to the operative site through the narrow portal. The multifunctional device is formed of an absorbent material, preferably expandable, having a substantially rigid dry state prior to introduction to the operative site and a soft, flexible wet state after absorbing fluids. The absorbent material can be formed witha spine therein of either a continuous or a discontinuous, segmented construction, and the spine can be branched and tubular or solid. The absorbent material can have portions or segments thereof expandable to different sizes to produce rounded protuberances to facilitate manipulation at the operative site and can have predetermined, non−straight configurations in the wet state, the predetermined configurations being controlled by the spine in the absorbent material or the method of forming the absorbent material. The multifunctional device can have a passage therethrough to accommodate laser, electrosurgical, biopsy or culturing instruments.

Abstract:
Source: US2002099289A A medical device for creating images of tissue within a body includes a disposable liquid−confining sheath supporting an elongate flexible drive shaft which carries an imaging device such as a ultrasound transducer. The device may include a trocar adapted to receive the sheath, the trocar permitting the device to be inserted into the body where no natural passageway exists, the trocar having a side−facing region adapted to maintain registry with the imaging device while the imaging device rotates. In another embodiment, the drive shaft includes an outer coil that is configured such that when the drive shaft is driven in the direction tending to decrease the diameter of the outer coil, the outer surface of the outer coil pressurizes liquid distally of the outer surface. The device optionally includes an inflatable balloon.

Abstract:
Source: CA2488588A Systems and methods for crossing stenosis, partial occlusions, or complete occlusions within a body lumen. The systems generally include an elongate member such as a hollow guidewire that houses a rotatable and translatable drive shaft. The drive shaft typically has a distal portion that is advanced to create a path in the occlusive material that is large enough to allow the hollow guidewire to cross the occlusive material.

Abstract:
Source: US2007219484A Catheter for aspiration, fragmentation and removal of removable material from hollow bodies, in particular of thrombi and emboli from human blood vessels, comprising a working head, a flexible transport screw, a flexible tube, and a cutting tool. The working head is independently displaceable along a guide wire, is arranged at the distal end of the catheter, and has at least one lateral opening. The flexible transport screw can be rotated at a distance by means of a rotary drive of a drive unit. The flexible tube surrounds the transport screw, is connected to the working head, and is intended for removing the detached thrombi and emboli fragments. The transport screw forms a shearing cutting tool in cooperation with the lateral opening of the working head, in order to comminute the detached thrombi and emboli between peripheral borders of the transport screw and borders of the lateral opening.

Abstract:
Source: US5330426A A device for intermixing a first component, such as a parenteral fluid with a second component, such as an immobilized drug carried by a scaffold to form a beneficial agent which, following the mixing step, can be dispensed directly from the device for infusion into a patient. The device includes novel mechanisms for mateably interconnecting a container, such as a glass vial containing the first component with a housing having a fluid outlet which houses a sealed container containing the second component, and then for controllably mixing the components under sterile conditions to form an injectable solution which is automatically dispensed through the fluid outlet of the device.

Abstract:
Source: US2002010462A A method of treating the heart and other body tissues by injecting a compound comprised of microsphere encapsulated macromolecule therapeutic agents into the myocardium, such that the microsphere size inhibits capillary transport of the compound but may permit lymphatic transport of the compound, and the compound releases therapeutic agents upon degradation of the microsphere.

Abstract:
Source: US5263940A An elastomeric bladder type infusion device for delivering a beneficial agent, such as a drug to a patient at substantially a constant rate. The device uniquely includes an internally disposed functional substrate which carries the beneficial agent so that it can be mixed with the fluid as the fluid is being introduced into the device to distend the bladder to make it an energy source for controllably dispensing the solution mixture to a patient.

Abstract:
Source: US3762648A A spray nozzle especially useful as a showerhead operable to deliver an intermittently interrupted or pulsating spray. Water passing through the device is divided within the device into two flow paths which are recombined prior to discharge through groups of nozzle orifices. Water flowing through one of the flow paths is directed against a turbine blade assembly to drive a rotatable valve rotor in rotation at a rotary speed dependent upon the pressure of water following this flow path. The second flow path bypasses the turbine blades, and hence water following the second flow path does not contribute to the rotary speed of the valve rotor. By adjustably throttling flow through the second flow path, the pressure head or driving force of water in the first flow path against the turbine blades may be varied to thus vary the rotary speed of the valve rotor independently of the supply pressure. Flow of water to each group of nozzle orifices is cyclically interrupted by the rotating valve rotor which connects only a portion of the orifices to supply at a given time. The configuration of the rotating valve port and the arrangement of the groups of nozzle orifices is such that back pressure at the rotating valve port remains constant regardless of the rotary position of the valve port.

Abstract:
Source: US2001044632A An emboli capturing system captures emboli in a body lumen. A first elongate member has a proximal end and a distal end. An expandable emboli capturing device is mounted proximate the distal end of the first elongate member, and is movable between a radially expanded position and a radially contracted position. When in the expanded position, the emboli capturing device forms a basket with a proximally opening mouth. A second elongate member has a proximal and a distal end with a lumen extending therebetween. The lumen is sized to slidably receive a portion of the first elongate member. An expandable delivery device is mounted to the distal end of the second elongate member and is movable from a radially retracted position to a radially expanded position. The delivery device has a receiving end configured to receive the emboli capturing device, and retains at least the mouth of the emboli capturing device in a radially retracted position.

Abstract:
Source: US5234456A A stent for placement within a body lumen and comprising a wall structure wherein at least a portion thereof is a hollow wall. The hollow wall has disposed therein a hydrophilic material which can be in the

form of a gel, for example, which swells upon introduction of a liquid into the hollow wall to thereby achieve inflation thereof. The hollow wall is fabricated of a semi−permeable membrane whereby fluid from tissues surrounding the stent at the site of placement can pass through the membrane and swell the hydrophilic material to thereby inflate the hollow wall. A drug can be disposed with the hydrophilic material for release through the membrane at the site of stent placement. The entire wall structure of the stent can be a hollow wall, or the wall structure can incorporate both hollow and non−hollow wall portions such as hollow and solid fibers which are braided, woven or wound together.

Abstract:
Source: US2002026231A Stented tubular grafts of expanded, sintered polytetrafluoroethylene (PTFE). The stented PTFE grafts of the present invention include an integrally stented embodiment, an externally stented embodiment, and an internally stented embodiment. In each embodiment, the stent may be either self−expanding or pressure−expandable. Also, in each embodiment, the stent may be coated or covered with a plastic material capable of being affixed (e.g., heat fused) to PTFE. Manufacturing methods are also disclosed by the individual components of the stented grafts are preassembled on a mandrel and are subsequently heated to facilitate attachment of the PTFE layer(s) to one another and/or to the stent. Optionally, the stented graft may be post−flexed and post−expanded following it's removal from the mandrel to ensure that the stented graft will be freely radially expandable and/or radially contractible over it's full intended range of diameters.

Abstract:
Source: US2006163515A A fluid handling device, such as a needlefree access device, includes a housing having an inlet and an inlet channel; and a flow control member comprising a combination outlet, biasing and piston member. The flow control member includes a piston section moveable between a closed position in which the piston section is inside the housing below the inlet channel but allows fluid to flow through the inlet channel; a biasing section connected to the piston section that normally biases the piston section into the inlet channel; and an outlet section connected to the biasing section having an outlet fitting in fluid communication with the inside of the housing.

Abstract:
Source: US2004199052A An endoscopic imaging system includes a reusable control cabinet having a number of actuators that control the orientation of a lightweight endoscope that is connectable thereto. The endoscope is used with a single patient and is then disposed. The endoscope includes an illumination mechanism, an image sensor and an elongate shaft having one or more lumens located therein. A polymeric articulation joint at the distal end of the endoscope allows the distal end to be oriented by the control cabinet. The endoscope is coated with a hydrophilic coating that reduces its coefficient of friction and because it is lightweight, requires less force to advance it to a desired location within a patient.

Abstract:
Source: US5820767A Use of a disposable filtration capsule with a non−occluded membrane filter element in the place of a standard spiral wound cartridge allows for the more rapid and quantitative filtration, recovery, and quantitation of microorganisms in liquid, particularly surface waters, well water, tap water, and the like. The capsule allows a severe reduction in the water sample size tested, substantially minimizes risks of cross−contamination, and provides a leak−proof vessel for shipment. Risk of infection of laboratory personnel and time of analysis are both reduced. Costs of measuring contamination by microorganisms such as Giardia and Cryptosporidium is lowered significantly while increasing the accuracy and dependability of the measurement.

Abstract:
Source: US2002081657A The invention provides isolated nucleic acids molecules, designated 21784 nucleic acid molecules, which encode novel calcium channel members. The invention also provides antisense nucleic acid molecules, recombinant expression vectors containing 21784 nucleic acid molecules, host cells into which the expression vectors have been introduced, and nonhuman transgenic animals in which a 21784 gene has been introduced or disrupted. The invention still further provides isolated 21784 proteins, fusion proteins, antigenic peptides and anti−21784 antibodies. Diagnostic methods utilizing compositions of the invention are also provided.

Abstract:
Source: US5527282A A vascular dilatation device for enlarging a flow passage in an obstruction in a vessel carrying flowing blood. A flexible cylindrical dilatation member is provided for placement in the obstruction and has first and second ends and an intermediate portion between the first and second ends with an interior flow passage extending therethrough having a diameter and a longitudinally extending central axis. The diameter of the flow passage is variable with movement of the first and second ends relative to each other along the longitudinally extending central axis from a contracted position to an expanded condition. The flexible cylindrical dilatation member is comprised of a plurality of flexible elongate elements each of which extends helically about the longitudinally extending central axis. First and second collars respectively engage the first and second ends of the flexible cylindrical dilatation member to retain the first and second ends in contracted positions. A mechanism is provided for causing relative axial movement of the first and second ends towards each other to cause an intermediate portion of the flexible cylindrical dilatation member to expand to form a rigid cylinder and thereby enlarge the obstruction spaces between the flexible elongate elements at the first and second ends so that blood in the vessel can continue to flow through said first and second ends and through the interior flow passage.

Abstract:
Source: US2003138378A A method, apparatus and probe for examining tissue for the presence of target cells, particularly cancerous cells, by subjecting the tissue to be examined to a contrast agent containing small particles of a physical element conjugated with a biological carrier selectively bindable to the target cells. Energy pulses are applied to the examined tissue. The changes in impedance and/or optical characteristics of the examined tissue produced by the applied energy pulses are detected and utilized for determining the presence of the target cells in the examined tissue. In a described preferred embodiment, the applied energy pulses include laser pulses, and the physical element conjugated with a biological carrier is a light−sensitive semiconductor having an impedance which substantially decreases in the presence of light. The same probe used for detecting the targeted cells may also be used for destroying the cells so targeted.

Abstract:
Source: US2011036240A In accordance with at least selected embodiments of the present invention, an improved liquid degassing membrane contactor or module includes a high pressure housing and at least one degassing cartridge therein. It may be preferred that the high pressure housing is a standard, ASME certified, reverse osmosis (RO) or water purification pressure housing or vessel (made of, for example, polypropylene, polycarbonate, stainless steel, corrosion resistant filament wound fiberglass reinforced epoxy tubing, with pressure ratings of, for example, 150, 250, 300, 400, or 600 psi, and with, for example 4 or 6 ports, and an end cap at each end) and that the degassing cartridge is a self−contained, hollow−fiber membrane cartridge adapted to fit in the RO high pressure housing.

Abstract:
Source: US2005159739A A brush electrode and a method for using the brush electrode for tissue ablation are disclosed. The brush electrode comprises a plurality of flexible filaments or bristles for applying ablative energy (e.g., RF energy) to target tissue during the formation of spot or continuous linear lesions. Interstitial spaces are defined among the filaments of the brush electrode, and the interstitial spaces are adapted to direct conductive or nonconductive fluid, when present, toward the distal ends of the brush filaments. The brush electrode facilitates electrode−tissue contact in target tissue having flat or contoured surfaces. The flexible filaments may be selectively trimmed to give a desired tip configuration or a desired standoff distance between the tissue and the conductive filaments in the brush electrode. Also, the filaments may be grouped into clusters. A shielded−tip brush electrode, including a flexible boot, is also disclosed.

Abstract:
Source: US2003171744A An intradiscal device for treatment of a patient's intervertebral disc. The device has two elongate probes for insertion to two spaced apart treatment sites of the annulus fibrosus. The distal portions of each probe have energy delivery means for delivering energy between the distal portions of the probes through the annulus fibrosus adjacent the two treatment sites. The energy is preferably electrical energy the probes may be inserted surgically through respective elongate introducer tubes.

Abstract:
Source: US2012330314A The present disclosure relates to devices and methods for creating channels within bone. One method for treating bone generally includes traversing an elongated member through cancellous bone of a vertebral body along a first generally non−linear path and then retracting the elongated member, thereby leaving a generally non−linear channel. The elongated member then is traversed through the cancellous bone along a second generally non−linear path, which second path does not completely coincide with the first path and then retracted along the second generally nonlinear path, thereby leaving a second generally non−linear channel. Optionally, bone filler material is deployed into the channels.

Abstract:
Source: US2004146650A Various embodiments of the invention present techniques for forming structures via a combined electrochemical fabrication process and a thermal spraying process or powder deposition processes. In a first set of embodiments, selective deposition occurs via masking processes (e.g. a contact masking process or adhered mask process) and thermal spraying or powder deposition is used in blanket deposition processes to fill in voids left by selective deposition processes. In a second set of embodiments, after selective deposition of a first material, a second material is blanket deposited to fill in the voids, the two depositions are planarized to a common level and then a portion of the first or second materials is removed (e.g. by etching) and a third material is sprayed into the voids left by the etching operation. In both embodiments the resulting depositions are planarized to a desired layer thickness in preparation for adding additional layers.

Abstract:
Source: US2002019661A A biodegradable stent for implantation into a lumen in a human body. The stent in one embodiment is made from a biodegradable fiber having an inner core and an outer layer. The outer layer is a blend of two polymer components. The inner core has a first degradation rate, and the outer layer has a second degradation rate. The second degradation rate is slower than the first degradation rate. The fiber softens in vivo such that the stent is readily passed from the lumen as a softened fragment or filament after a pre–determined period of time through normal flow of body fluids passing through the lumen.

Abstract:
Source: US5246371A A method and apparatus for delivery of highly filled, thixotropic resin sealant to tooth surfaces. The apparatus includes a dispenser for holding a quantity of the sealant material and a delivery tip having adjustable bristles at one end. The bristles are slidably secured in a spiral passageway formed by a helical ridge inside the delivery tip, thereby allowing the sealant material to be continuously applied without the need to stop the procedure and rewet the applicator. The applicator permits accurate control of the amount of sealant material applied to the surface. In this way, the surface receives neither an excessive nor an insufficient amount of the sealant material. Moreover, the bristles may be pushed in to permit the sealant material to be applied to a small, irregular surface, such as pits and fissures, or pulled out to permit the bristles to fan out for application to broad surface areas. Delivery of highly filled, relatively viscous, thixotropic sealant materials is made possible by providing the spiral passageway around the bristles so that the coating material does not have to flow through the bristles, and due to sheer thinning caused by forcing the thixotropic material through the spiral passageway.

Abstract:
Source: US2012296353A A graft device is provided comprising a flow conduit and a surrounding covering. The graft device is for connecting between a first body space and a second body space. In one embodiment, the flow conduit is a vein, such as a harvested saphenous vein, useful as an arterial graft, for example and without limitation, in a coronary artery bypass procedure. Also provided are methods of preparing a graft device and connecting the graft between a first body space and a second body space, such as the aorta and a location on an occluded coronary artery, distal to the occlusion.

Abstract:
Source: US2009143770A A medical luer connection improves liquid mixing thereby reducing areas of low or stagnant flow within the plenum chamber formed between the male and female luer connectors. Stagnation or low flow areas in the plenum can be reduced by imparting a non−axial flow component to the fluid flow as it passes through the plenum. Improvement of the cleaning effectiveness of the luer connection reduces the amount of flushing fluid needed to clean the connection, reduces the residual blood matter at a fixed volume of fluid relative to a standard luer connection, or combinations of the above.

Abstract:
Source: GB745914A 745,914. Ventilating aircraft. HELMORE, W. Feb. 26, 1954 [Jan. 28, 1953; Feb. 4, 1953], Nos. 2503/53 and 3200/53. Class 137. [Also in Groups XI and XIII] A heat–exchanger comprises at least one curved or spiral passage formed by bending sheet material, a spacing element being disposed in and extending along substantially the whole length of said passage and being so shaped as to make contact with the passage walls at a number of locations distributed over substantially the whole area thereof. The spacing element may comprise sheet material slit and corrugated or it may comprise reticulated material in the form of a corrugated grid or it may comprise a plurality of wire coils. The spacing element may alternatively comprise tubular heating or cooling means in the form of a coil or it may be an electric heater coil. Fig. 3 shows an arrangement for heating or cooling air for the interior of an aircraft in which both the air and the heating or cooling fluid flow in spiral paths defined by sheets 18, 19. The spacing elements between the plates 18, 19 are not shown. Hot oil engine exhaust gases and liquid air are mentioned as suitable heating and cooling media. The heating or cooling medium enters the heat–exchanger at 43 and is discharged at 44 whilst air to be heated or cooled enters the heat exchanger by way of an opening controlled by a valve 40 and after passing through the heat–exchanger is discharged by way of openings controlled by valves 38, 42 either through a nozzle 36 to the aircraft or back into the atmosphere. The valves 38, 40, 42 may be thermostatically controlled in accordance with the temperature in the aircraft.

Abstract:
Source: US5250071A This invention is a surgical instrument and specifically is a device for delivering an embolic coil to a selected site within the vasculature of a human body via use of a catheter. In particular, the device uses embolic coils having interlocking clasps on the coils which are secured to each other by a control wire within the catheter. Retraction of the control wire into the catheter body uncouples the distal coil.

Abstract:
Source: US5601537A Apparatus and methodology for applying catheters, dilators and occluders to mammalian genito−urinary and gastro−intestinal passages, using rotational manipulation of threaded or helically−formed catheters and threaded dilators and occluders. Threaded or helical catheters are inserted into the opening of the selected passage far enough to engage a thread segment, the other end of the catheter is then manually rotated to draw the catheter into the passage. Threaded dilators and occluders are similarly applied.

Abstract:
Source: US5769870A A plurality of embodiments of a distal perfusion device are disclosed, which device facilitates anastomosis constructions by maintaining a dry anastomosis site while simultaneously maintaining blood flow distally in the blood vessel to prevent ischemia and reduce overall patient trauma. The perfusion device is configured for installation into a blood vessel such as a left anterior descending coronary artery through an incision therein, to which is to be grafted a distal end of a blood vessel such as an internal mammary artery. The device includes a central member of selected configuration and material, terminating at either end thereof in respective selectively tapered end members. A lumen extending through the central member and end members, and selected perforations in the end members, maintain blood flow through the perfusion device. A selected portion or portions of the device's outer circumference fit snugly within the artery in the regions beyond and/or at the anastomosis site, to maintain the latter free of blood. Several methods for deploying and removing respective embodiments of the device also are illustrated.

Abstract:
Source: US2014200599A A rotary catheter for opening partially and totally obstructed bodily vessels of varying diameter (e.g., blood vessel) which comprises a motor–driven flexible hollow shaft rotatably disposed in a flexible tube, an aspiration channel defined between the flexible tube and the hollow shaft, a tip affixed to a distal end of the hollow shaft having a rounded distal end being rotatable and slideable over the guidewire, the tip having sides, a base and a crown that is offset away from a longitudinal axis of the hollow shaft further than the base and a distance between the sides being smaller than a distance between the crown and the base leaving open passages along the tip, the guidewire can be withdrawn proximally to allow the rotating crown to displace the distal end of the tip away from said wall of said vessel to tunnel through a total obstruction.

Abstract:
Source: US2002151979A Systems for minimally invasive disc augmentation include an anulus augmentation component and a nucleus augmentation component. Both are suited for minimally invasive deployment. The nucleus augmentation component restores disc height and/or replaces missing nucleus pulposus. The anulus augmentation component shields weakened regions of the anulus fibrosis and/or resists escape of natural nucleus pulposus and/or the nucleus augmentation component. Methods and deployment devices are also disclosed.

Abstract:
Source: US2002020663A A filter assembly and a method of filtering a fluid using the filter assembly are disclosed. The filter assembly includes wave coils arranged axially to define a filter element. The filter element includes bottom and top ends and an inner cavity. The filter assembly also includes a base plate that engages one, or both, ends to support the wave coils. The fluid flows toward the base plate, and the base plate diverts the fluid inside or outside the inner cavity. The wave coils include crests and troughs engaging one another on adjacent wave coils to define filtration apertures. The diverted fluid is filtered through the filtration apertures such that a filtrate of the fluid passes through the inside or outside of the inner cavity, and a retentate of the fluid is retained on the other of the inside or outside of the inner cavity relative to the filtrate.

Abstract:
Source: US2012209190A A repeater system may control a pump by using a repeater and a user interface. An adhesive patch system may be used for affixing a pump or other object to a human body. Such an adhesive patch system may include two sets of adhesive members, each member including an adhesive material on at least one side so as to attach to the body. The members of the first set are spaced to allow the members of the second set to attach to the body in spaces provided between the members of the first set, and the members of the second set are spaced to allow members of the first set to detach from the body without detaching the members of the second set. Also, fill stations and base stations are provided for personal pump systems.

Abstract:
Source: US2002056330A A lubricant supply device comprises application members, a casing and control members. The casing forms a lubricant storage member, which is divided into compartments arranged in the circumferential direction of the lubricant storage member. The number of the compartments is equal to or larger than the number of thread grooves of the screw shaft. The application members are placed in correspondence to

the compartments. Each of the application members has the single tongue portion.

Abstract:
Source: US2004143240A A catheter provided with an adjustable length guidewire catheter lumen, located proximal of a therapeutic device or agent positioned at the distal end of the catheter. The length of the adjustable length guidewire catheter lumen is controlled by the physician, allowing the benefits of both over−the−wire and rapid exchange systems to be provided in one catheter. The adjustable length is provided with a thin−walled tube that corrugates under axial compression. The tube may optionally be pre−corrugated or may be allowed to corrugate non−uniformly under the axial compression. The catheter length may change by, for example, over 100 percent of its original length between full axial compression and full axial extension.

Abstract:
Source: US2009240264A A suturing device for use with a delivery catheter in a transcatheter procedure, for closing an opening formed in the body. The suturing device comprises: a spiral needle having a central core, a proximal end, and a distal end. The distal end terminates in a sharp point for cutting a spiral passageway through body tissue surrounding the opening that is to be closed. The device also includes a guide wire having a suture eye at one end thereof for receiving suture thread after the guide wire has been advanced through the hollow central core of the spiral needle. The device further includes driving means, for allowing advancing and retracting of the spiral needle and guide wire with respect to the catheter, and for allowing connecting between the suture thread and the suture eye of the guide wire. The present invention also relates to a method for closing an opening formed in the body using a transcatheter procedure.

Abstract:
Source: US2011282285A An insertion tool for inserting a catheter into a body of a patient is disclosed. The insertion tool unifies needle insertion, guidewire advancement, and catheter insertion in a single device. In one embodiment, the insertion tool comprises a housing in which at least a portion of the catheter is initially disposed, a hollow needle distally extending from the housing with at least a portion of the catheter pre−disposed over the needle, and a guidewire pre−disposed within the needle. A guidewire advancement assembly is also included for selectively advancing the guidewire distally past a distal end of the needle in preparation for distal advancement of the catheter. In one embodiment a catheter advancement assembly is also included for selectively advancing the catheter into the patient. Each advancement assembly can include a slide or other actuator that enables a user to selectively advance the desired component.

Abstract:
Devices, methods and kits for preventing or reducing non–target microparticles deposition and embolization, in conjunction with delivering microparticles (e.g., embolization material) via a blood vessel to a target bodily part. Applicable for entrapping infiltrated microparticles within heart right atrium. Entrapping device includes: filter; and filter collapsing mechanism sized for positioning in catheter lumen of a filter delivering catheter, and having proximal end actuatable from outside of subject. Filter configured for positioning within heart right atrium, for self–expanding and covering right atrium inlet opening, and configured, when expanded, to collect embolic material delivered to target organ and infiltrated into outflow vessel thereof draining to right atrium. Filter collapsing mechanism configured for collapsing, and being manipulated to form a pocket in filter, to entrap collected embolic material therein, and drawing filter with collected embolic material in pocket, into catheter lumen of filter delivering catheter.

Abstract:
Source: US2002115997A An electrosurgical instrument and technique for creating thermal seal or welds transected margins of engaged tissue. The working end provides very elongate jaws particularly suited for resecting tissue, such as in a lung resection. The jaw assembly carries a bi−polar electrode arrangement that provides for Rf current flow to targeted tissue described as a subfascial−to−fascial (or medial−to−surface) bi−polar approach. The working end of the device carries an openable and closable jaw assembly with paired first and second jaws for engaging tissue. The paired jaws have an axial channel for receiving a sliding (blade) member for transecting the captured tissue. The paired jaws carry electrode surfaces having a common polarity so that Rf current will not flow d between the jaws which engage the surface or fascial tissue layers. Further, the transecting member had flange−type surface portions that extend over a substantial longitudinal length of the jaws to maintain very high compression on captured tissue even when the jaws have a very small cross section and hence may be somewhat flexible.

Abstract:
Source: US2002068924A Infrared surgical photoablation instruments are disclosed for creating lesions in tissue, including cardiac tissue for treatment of arrhythmias and other diseases. The hand held instruments are especially useful in open chest or port access cardiac surgery for rapid and efficient creation of curvilinear lesions to serve as conduction blocks. Photoablative instruments are disclosed that emit radiation at a wavelength in a range from about 800 nm to about 1000 nm, and preferably emit at a wavelength in a range of about 915 nm to about 980 nm. Radiation at a wavelength of 915 nm or 980 nm is commonly preferred, in some applications, because of the optimal absorption of infrared radiation by cardiac tissue at these wavelengths.

- List: SS3 1–50 (FT=occlu* and hollow and (channel or passage or bore) and (helix or spiral)) (Results 282)

Abstract:
Source: US2002111647A Disclosed is an adjustable occlusion device for use in a body lumen such as the left atrial appendage. The occlusion device is removably carried by a deployment catheter. The device may be enlarged or reduced to facilitate optimal placement or removal. Methods are also disclosed.

Abstract:
Source: US2009105722A Devices, methods, and systems facilitate and enable treatment of ischemic stroke. More specifically, a tethered basket−like system operates in conjunction with a microcatheter system, to provide arterial support and capture emboli.

Abstract:
Source: US2012089047A Catheter apparatuses, systems, and methods for cryogenically modulating neural structures of the renal plexus by intravascular access are disclosed herein. One aspect of the present application, for example, is directed to apparatuses, systems, and methods that incorporate a catheter treatment device

comprising an elongated shaft. The elongated shaft is sized and configured to deliver a cryo−applicator to a renal artery via an intravascular path. Cryogenic renal neuromodulation may be achieved via application of cryogenic temperatures to modulate neural fibers that contribute to renal function, or of vascular structures that feed or perfuse the neural fibers.

Abstract:
Source: US2014260928A Methods of forming a structure for treating a vessel include providing a mandrel and braiding a plurality of filaments around the mandrel. The mandrel may include a strand having a longitudinal axis and a plurality of balls coupled to the strand along the longitudinal axis. Pairs of the plurality of balls may be spaced along the longitudinal axis. Braiding the plurality of filaments around the mandrel may include, during braiding, forming a plurality of bulbs around the plurality of balls and forming necks between pairs of the plurality of balls. The methods may include, after braiding the plurality of filaments, heat treating (e.g., shape setting) the plurality of filaments on the mandrel. Portions of the braided plurality of filaments may be secured to the mandrel, for example using bangles, wire, and/or adhesive.

Abstract:
Source: US2014216258A The instant application relates to a high pressure spiral–type hollow fiber membrane fabric–containing module or contactor, comprising: a high pressure module housing or vessel; a pair of end caps; liquid end ports and at least one gas port; and at least one membrane cartridge, wherein each module or contactor has one or more shims, spacers, protrusions, and/or the like on a cartridge shell exterior, on a module housing interior, on the cartridge shell exterior and on the module housing interior, and/or between the shell and

the housing.

Abstract:
Source: US2005020974A A steerable distal support system for accessing stenosis, partial occlusions, or complete occlusions within a body lumen. The steerable distal support system generally includes an elongate member that comprises a proximal portion, a more flexible intermediate portion and a deflectable distal tip. The deflectable distal tip is at a distal end of the elongate body to facilitate directionality and positioning of the steerable distal support system to the target site. Optionally, an expandable centering assembly may be disposed on the steerable support assembly to center and anchor the steerable support assembly within the body lumen.

Abstract:
Source: US2005075584A Methods and systems for minimally invasive replacement of a valve. The system

includes a collapsible valve and anchoring structure, devices and methods for expanding the valve anchoring structure, adhesive means to seal the valve to the surrounding tissue, a catheter–based valve sizing and delivery system, native valve removal means, and a temporary valve and filter assembly to facilitate removal of debris material. The valve assembly comprises a valve and anchoring structure for the valve, dimensioned to fit substantially within the valve sinus.

Abstract:
Source: US5379603A Prechilling the tap water with the cold waste water from an ice machine is achieved by using an insulated, elongated casing, which encloses a reservoir housing a heat exchanger made of a relatively long tubing of copper to provide a relatively long path of travel for the tap water. The heat exchanger is in the form of a coil followed by a substantially straight tube within and surrounded by the coil's turns. A hollow member, closed at one end, is spaced from the straight tube. The coil's turns surround the hollow member and the straight tube. Preferably, the hollow member is mounted over and is spaced from the straight tube to form there between an elongated chamber. In use, the tap water flows downwardly in the coil and upwardly through the straight tube. The cold waste water flows through the elongated chamber into the reservoir, thereby progressively and continuously increasing the temperature of the waste water and correspondingly decreasing the tap water's temperature.

Abstract:
Source: US2016235337A A guidewire, consisting of a hollow tube, containing a longitudinal lumen and having a spiral channel cut into the tube, and having a distal end. The guidewire has an elongate flexible core positioned within the longitudinal lumen. The guidewire also has a conductive coil, wound around the core at a location within the lumen in proximity to the distal end, that is coupled to output a signal in response to a magnetic field applied to the guidewire.

Abstract:
Source: US3906937A A blood−pressure cuff comprises an elongated non−elastic cover having an inflatable portion in which is disposed an inflatable bladder. Means extends from the inflatable portion for fastening the cover when the inner surface of the inflatable portion is applied to a limb of the user preparatory to inflation of the bladder. An integral, prestressed resilient clip of spiral shape is freely disposed in the inflatable portion of the cover between the bladder and outer cover surface to impart its spiral shape to both the inflatable portion of the cover and the bladder therein. The inflatable bladder may have a plurality of contiguous chambers each in fluid communication with adjoining chambers and a single fluid inlet adapted to have fluid under pressure supplied to the chambers for inflating the chambers.

Abstract:
Source: US2004074757A A method and device for enhancing distillation in an evaporator. The evaporator includes phase change chambers, such as vertically−oriented cylindrical evaporation tubes. Each chamber has an evaporation region that can be heated externally. Each chamber has an inlet for introducing liquid to the chamber and an outlet opening for allowing vapor to exit from the chamber. Packing is inserted into one or more chambers to enhance distillation. The packing may include a rod with bristles emanating from the rod. Other chamber packing may include multiple rods or a mesh.

Abstract:
Source: US2015075137A A catalytic converter assembly has a substrate body with a plurality of cells for passage therethrough of exhaust gases. Metal is located at predetermined locations in the substrate body. An electromagnetic field generator is mounted adjacent the substrate for generating a varying electromagnetic field inductively to heat the metal and so heat the substrate.

Abstract:
Source: US2009069759A An apparatus (1) for cleansing wounds (5) in which irrigant fluid from a reservoir connected to a conformable wound dressing (2) and wound exudate from the dressing are moved by a device (18) (which may be a single pump or two pumps) for moving fluid through a flow path (6, 7, 9, 10) which passes through the dressing with a means for providing simultaneous aspiration and irrigation of the wound, and means for supplying thermal energy to the fluid in the wound. The former provides a desired balance of fluid at a controlled nominal flow rate that removes materials deleterious to wound healing, while distributing materials that are beneficial in promoting wound healing over the wound bed. The latter maintains a temperature at the wound bed under the wound dressing at a level that promotes wound healing.

Abstract:
Source: US2003074052A The present invention is directed to bistable cells and their use in devices, particularly medical devices such as stents, clamps and valves. An expandable stent formed of a plurality of bistable cells is described. The stent has two or more stable configurations, including a first stable configuration with a first diameter and a second stable configuration with a second, larger diameter. A valve comprising a bistable cell for use in eliminating incontinence is also disclosed.

Abstract:
Source: US2003000907A A beverage container is provided with a hydrophobic vent consisting of a relatively thick and rigid disc−shaped piece of macroporous plastic having pore sizes averaging from 7−350 microns. The vent can be welded, molded or secured to the sidewall, bottom or cap of a plastic beverage container thus eliminating all moving parts. The macroporous plastic is resistant to oxidative abrasion, contamination and wetting and is strong enough to resist breakage. In one embodiment a baby bottle is provided which consists of a plastic bottle body, a nipple, and means for fastening the nipple to the bottle body. The bottle body is provided with a macroporous plastic vent which can be welded, molded or secured to the sidewall or bottom of the bottle body thus eliminating all moving parts. The bottle body can be washed repeatedly as a single unit with the vent intact.

Abstract:
Source: US2005267408A The invention includes a catheter having an elongate main body having a proximal section and a distal section. The elongate main body further includes a first guidewire lumen and a second guidewire lumen. Each guide wire lumen including a proximal port and a distal port in communication with an external environment. The proximal port of the first guidewire lumen spaced by a gap from the distal port of the second guidewire lumen. In accordance with a further aspect of the invention, the catheter includes a plurality of overlapping stiffening members defined along at least a portion of a length between the distal end and the proximal end of the elongate main body.

Abstract:
Source: US2012247337A The present invention is directed to contactors, modules, components, systems, and/or methods of manufacture, and/or methods of use including degassing liquids. The contactor or module is integrally potted, has planar, disc shaped end caps, and a cylindrical housing or shell receiving and supporting a membrane

structure. Each of the planar disc shaped end caps has a central opening therein adapted to receive a liquid end port or nozzle and is held in place in the housing or shell by at least one retaining element. The integrally potted membrane structure is preferably potted in place in the housing or shell by an inverted potting process involving the use of a removable plunger or plug to recess the potting.

Abstract:
Source: US2003153931A A device for connecting hollow organs and/or sealing wall defects in hollow organs, has a base mounting for replacement on a hollow organ. The base mounting has at least one recess on a first surface and at least one guidetrack for at least one spiral needle in which the spiral needle is movable forwards in a rotatable fashion. The guidetrack for the spiral needle is disposed at least partially along the edge of the recess in such a manner that the track of the spiral needle during a revolution extends partially in the base mounting and partially in the recess.

Abstract:
Source: US2004167634A The invention is directed to a prosthetic kidney, to methods of making a prosthetic kidney and to methods of treating kidney disease with a prosthetic kidney. The prosthetic kidney comprises nephron analogs on the exterior surface and an enclosed porous membrane structure equipped with an effluent channel for collecting and draining urine from the device. The nephron analogs are prepared by implanting a device containing renal tubule analogs on the membrane structures and inducing angiogenesis to form glomeruli–like structures. The renal tubule analogs are prepared by seeding kidney cells on the porous membrane structure and culturing this composite in vitro.

Abstract:
Source: US2006069346A A method and device for treating a Chronic Total Occlusion provides a controllable stiffness catheter with a shaft having a stiffness sheath and an access lumen. The device has a stiffness device in a stiff state below a given temperature and in a soft state above the temperature, a temperature−changing device in thermal contact with the stiffness device, the temperature−changing device changing a temperature of the stiffness device below and above the temperature, and a power controller electrically connected to the stiffness device and selectively supplying power to the temperature−changing device to change a stiffness of the stiffness device between the stiff and soft states. A guidewire is moved to a treatment site and the catheter moves along the guidewire up to CTO in its soft state. The catheter stiffens without straightening and, in the stiff state, the catheter or the guidewire is projecting through the CTO.

Abstract:
Source: US2012222551A A process for reducing the loss of valuable products by improving the overall recovery of a contaminant gas component in swing adsorption processes. The present invention utilizes at least two adsorption beds, in series, with separately controlled cycles to control the adsorption front and optionally to maximize the overall capacity of a swing adsorption process and to improve overall recovery a contaminant gas component from a feed gas mixture.

Abstract:
Source: US4820626A The present invention provides a novel method of treating a synthetic or naturally occurring implant, such as a vascular graft, intended for implantation in a human patient, comprising obtaining human microvascular rich tissue from that patient; separating microvascular endothelial cells from that tissue; and placing said microvascular endothelial cells onto said implant to provide at least about 50 percent confluence of said cells on the surface of said implant to be treated. In the preferred embodiment, the microvascular rich tissue is perinephric fat, which is obtained from the donor and subjected to a digestive separation process to provide an abundant supply of microvascular endothelial cells. In the preferred embodiment, these microvascular endothelial cells are placed onto the implant by suspending them in a protein (plasma) containing physiologic saline solution, which is incubated on the graft until the endothelial cells either adhere to the graft surface or clot within the protein solution. An efficient method is therefore provided which will permit a patient to donate excess microvascularized tissue which may be used to procure autologous endothelial cells which are subsequently used to treat a graft or other implant to provide at least 50 percent confluence while his related surgical procedure is in progress.

Abstract:
Source: US2016000501A Embodiments of medical devices and methods are disclosed. The medical devices typically comprise a flexible elongate member defining a lumen, and a support spine affixed to the distal end and extending proximally therefrom within the elongate member lumen. In some embodiments, the support spine is configured to support at least a portion of the elongate member when the elongate member is bent or curved. Some embodiments include apertures at or near the distal end for enabling fluid communication between the lumen and the outside environment. In some embodiments, the support wire extends proximally from the distal end within a distal portion of the lumen such that a proximal portion of the lumen is substantially unobstructed, thereby reducing turbulence of fluid flowing through the lumen.

Abstract:
Source: US2002082641A A vascular clip includes a peripheral body defining a plane, and tines extending from the body transversely with respect to the plane, the tines biased towards a planar configuration. The clip includes expandable elements disposed along its periphery that are biased to expand from compressed to expanded states for increasing a diameter of the clip upon deployment. The clip is provided within a housing slidably mounted on an introducer sheath. The sheath is introduced through a puncture into a blood vessel, and after a procedure is performed via the sheath, the housing is advanced into the puncture and the clip deployed until the tines engage tissue adjacent the opening in the vessel wall. The sheath is withdrawn from the patient, leaving the clip in place. The tines at least partially move towards the planar configuration to pull the engaged tissue together and close the opening.

Abstract:
The support probe is formed as a hollow probe (1), at least one channel of which is connected with the hollow chamber (12) of the hollow spiral (2). The hollow spiral at its front end has an aperture (10) for accommodation of a guide wire (11). Also at the front end of the hollow spiral is a rounded point closing the hollow chamber and enabling a non–traumatic introduction of the probe. The distances between adjacent spiral windings are variable by means of a draw string in the centre of the hollow probe and which is fixed to the rounded point.

Abstract:
Source: US2008282888A The adsorption of CO_2 from flue gas streams using temperature swing adsorption. Adsorbent contactors are used in the temperature swing adsorption unit that contain a plurality of substantially parallel channels comprised of or coated with an adsorbent material that is selective for adsorbing CO_2 from flue gas.

Abstract:
Source: US4115273A An extracorporeal, disposable, dialyzer for use in a variety of artificial kidney or other mass transfer systems, which includes a sheet of plastic material supporting a flattened tube of membrane material, the sheet of support material consists of a continuous sheet of contoured, substantially uniform thickness material including a series of spaced apart hollow protrusions extending outwardly from each side thereof, the summits of the hollow protrusions defining membrane support surfaces on each side of the sheet, and the summits being arranged with respect to each other in predetermined wave patterns dimensioned and arranged such that, when

an elongated length of the sheet is formed into a roll having predetermined inner and outer peripheral dimensions, the wave patterns will never be directly superimposed thereby avoiding the tendency of corresponding hollow protrusions to interdigitate and occlude the fluid flow passages.

Abstract:
Source: US2007235050A A smoking article filter includes a flow restrictor and a cavity downstream of the flow restrictor. The flow restrictor includes an orifice or flow channel for directing smoke into the cavity. The filter is attached to the tobacco rod with tipping paper and includes an air−admissible ventilating zone at a location downstream of the restrictor.

Abstract:
Source: US5538642A PCT No. PCT/US92/03650 Sec. 371 Date Oct. 19, 1994 Sec. 102(e) Date Oct. 19, 1994 PCT Filed May 1, 1992 PCT Pub. No. WO93/22038 PCT Pub. Date Nov. 11, 1993Spiral wound membrane elements have permeate flow channels attached to a porous polymeric mandrel in a regular and closely spaced array. The permeate flow channels are attached to the mandrel by means of ultrasonic welding. The attaching

means permits the attachment of a high density of permeate flow channels.

Abstract:
Source: US2005223885A The hydraulic distributor exhibits a cylindrical and internally–hollow body (**2**) having an inlet chamber (**3**) for a fluid and an outlet chamber (**4**) which are interconnected directly (by a communication conduit), or indirectly by an external distributor. A cursor (**7**) is axially mobile in the hollow body (**2**) and a closing element (**12**) is associated to the cursor (**7**) by elastic elements (**11**). The closing element (**12**) is mobile in the inlet chamber (**3**) between a first position in which it occludes the inlet chamber (**3**) and a second position in which it permits passage of fluid from an antechamber (**3***a*) to a second opening (**3***b*).

Abstract:
Source: US2002095206A An expandable stent comprised of a plurality of helical segments is disclosed. In one embodiment, the stent is generally cylindrical in shape having a cylindrical axis, and the comprises at least two a first and second set of helical segments. The helical segments in the first set are substantially parallel and have a first pitch forming a first helical angle with respect to the cylindrical axis. The helical segments in the second set are also generally parallel to each other and form a second pitch that differs from the first pitch, thereby forming a second helical angle with respect to the cylindrical axis. In an alternative embodiment, the stent comprises one set of helical segments and a plurality of circumferential elements that are joined together by the helical segments to form a plurality of cylindrical elements which are joined together to form a stent body. The stent may also have endzones.

Abstract:
Source: US2014081298A The invention provides a rotational atherectomy device having, in various embodiments, a flexible, elongated, rotatable drive shaft with a system of eccentric abrading heads attached thereto. At least part of the eccentric enlarged abrading heads in the system have a tissue removing surface−the abrading heads may be at least partially hollow. Preferably the abrading heads have centers of mass spaced radially from the rotational axis of the drive shaft, facilitating the ability of the system of abrading heads to work together to open the stenotic lesion to a diameter larger than the outer resting diameter of the abrading heads when operated at high speeds. Therefore, certain embodiments comprise a system having unbalanced centers of mass to not only stimulate greater rotational diameters but also arranged in a manner whereby a debris−removing augering effect occurs. Other embodiments may comprise systems having abrading heads with balanced centers of mass.

Abstract:
Source: US6699331B Apparatus for wiping a contaminated lumen of an endoscope including a cleaning member having at least one radially extending fin for passing axially through the lumen with at most a small clearance whereby contamination remaining after passage of the member through the lumen is substantially uniformly distributed as a thin film on an internal wall of the lumen. The invention also relates to a method for cleaning a contaminated lumen of an endoscope including pulling or pushing a cleaning member axially through the lumen and treating the uniformly distributed film with a cleaning composition.

Abstract:
Source: US2003160774A In an output setup to a device apparatus, when the contents of a plurality of setting items are changed in a lump by using a compound setup consisting of a plurality of setting items, a mismatching of the set contents and a function of the device apparatus is avoided. For this purpose, according to the invention, when the compound setup can be used for a plurality of device apparatuses, the compound setup which is used for the designated device apparatus is selected, and in case of performing the output setup to the designated device apparatus by using the selected compound setup, whether the output can be performed by the contents of each setting item of the compound setup in the device apparatus or not is discriminated in accordance with the function of the device apparatus.

Abstract:
Source: US2004193147A Methods and apparatus for treatment of patent foramen ovale (PFO) provide for applying energy to tissues adjacent the PFO with a catheter device to substantially close the PFO acutely. Apparatus generally includes a catheter device having at least one energy transmission member at or near its distal end configured to apply energy to PFO tissues to acutely, substantially close the PFO. Applied energy may

be monoploar or bipolar radiofrequency energy or any other suitable energy, such as laser, microwave, ultrasound, resistive heating or the like. Some embodiments of a catheter device further include one or more tissue apposition members near the distal end for helping bring PFO tissues together, such as a PFO covering member, a vacuum applying member and/or the like. PFO closure via energy−based approaches of the invention may help prevent stroke, treat migraine headache, and possibly treat or prevent other medical conditions.

Abstract:
Source: US5399352A A device for the local delivery of a substance into a natural tissue conduit in the mammalian body, having a first clement capable of contacting the lumen of the conduit and a second element which overlays first element, a reservoir being formed between the first element and the second element, the interior of the reservoir being capable of fluid communication with the conduit such that a substance placed in the reservoir is delivered into the conduit. Also provided are methods of locally delivering a substance into a natural tissue conduit in the mammalian body utilizing the device of the present invention.

Abstract:
Source: US2012209217A A repeater system may control a pump by using a repeater and a user interface. An adhesive patch system may be used for affixing a pump or other object to a human body. Such an adhesive patch system may include two sets of adhesive members, each member including an adhesive material on at least one side so as to attach to the body. The members of the first set are spaced to allow the members of the second set to attach to the body in spaces provided between the members of the first set, and the members of the second set are spaced to allow members of the first set to detach from the body without detaching the members of the second set. Also, fill stations and base stations are provided for personal pump systems.

0) US2001010107A – UPRIGHT VACUUM CLEANER WITH CYCLONIC AIR FLOW

Abstract:
Source: US2001010107A An upright vacuum cleaner includes an upright housing section and a nozzle section. A cyclonic airflow dirt and dust separating chamber is defined in said upright housing section. A suction source pulls air and entrained dirt, dust, and other contaminants through a main suction opening formed in the underside of the nozzle and into the cyclonic airflow chamber. The cyclonic airflow chamber causes the suction airstream to travel in a cyclonic path such that the entrained contaminants are separated therefrom and deposited into a dirt container that defines the chamber. A main filter element filters residual contaminants from the suction airstream between the chamber and the suction source. The main filter element is preferably made from high−density polyethylene porous filter media. A final filter assembly filters the suction airstream discharged by the suction source to ensure that the air discharged into the atmosphere is contaminant free, including those contaminants introduced into the airstream by the suction source itself.

Abstract:
Source: US2006089633A Methods and apparatus are provided for selective surgical removal of tissue, e.g., for enlargement of diseased spinal structures, such as impinged lateral recesses and pathologically narrowed neural foramen. In one variation, tissue may be ablated, resected, removed, or otherwise remodeled by standard small endoscopic tools delivered into the epidural space through an epidural needle. Once the sharp tip of the needle is in the epidural space, it is converted to a blunt tipped instrument for further safe advancement. A specially designed epidural catheter that is used to cover the previously sharp needle tip may also contain a fiberoptic cable. Further embodiments of the current invention include a double barreled epidural needle or other means for placement of a working channel for the placement of tools within the epidural space, beside the epidural instrument. The current invention includes specific tools that enable safe tissue modification in the epidural space, including a barrier that separates the area where tissue modification will take place from adjacent vulnerable neural and vascular structures. In one variation, a tissue abrasion device is provided including a thin belt or ribbon with an abrasive cutting surface. The device may be placed through the neural foramina of the spine and around the anterior border of a facet joint. Once properly positioned, a medical practitioner may enlarge the lateral recess and neural foramina via frictional abrasion, i.e., by sliding the abrasive surface of the ribbon across impinging tissues. A nerve stimulator optionally may be provided to reduce a risk of inadvertent neural abrasion. Additionally, safe epidural placement of the working barrier and epidural tissue modification tools may be further improved with the use of electrical nerve stimulation capabilities within the invention that, when combined with neural stimulation monitors, provide neural localization capabilities to the surgeon. The device optionally may be placed within a protective sheath that exposes the abrasive surface of the ribbon only in the area where tissue removal is desired. Furthermore, an endoscope may be incorporated into the device in order to monitor safe tissue removal. Finally, tissue remodeling within the epidural space may be ensured through the placement of compression dressings against remodeled tissue surfaces, or through the placement of tissue retention straps, belts or cables that are wrapped around and pull under tension aspects of the impinging soft tissue and bone in the posterior spinal canal.

Abstract:
Disposable intra–arterial auger and dotter instruments (20) for use in patients in clearing pathways at obstructed or nearly obstructed arterial sites are disclosed. A number of auger tips (400, 402, 470, 490, 600, 700) used on the instruments are disclosed along with a method for releasibly affixing auger tips to the instruments. In addition, a dotter tip (520, 550, 560) is disclosed for use in procedures where it is desired to open a pathway without excising material from the obstructed site. A combined auger and dotter tip (750) is disclosed for a procedure in which material displacement followed by excising of material from within an artery is accomplished without removal of the combined auger and dotter tip until the procedure is complete.

Abstract:
Source: GB863643A 863,643. Discharge lamps. GENERAL ELECTRIC CO. Ltd. April 10, 1959 [April 22, 1958], No. 12722/58. Class 39(1). A discharge lamp comprises an envelope tube 1, of circular or oval cross–section, filled with a starting rare gas and with sodium vapour at low pressure–less than 1 mm. and about 0.01 mm., the envelope being mounted, or arranged to be mounted, within at single or double walled evacuated outer jacket 3 and having, over at least the greater –part of its overall length, substantially the form of a helically coiled tube including at least two complete turns, such overall length measured in a direction parallel to the helical axis being greater than the overall width of the envelope. The helically Coiled part of the tube 1 can be in the form of a single–start helix having a pitch which is not more than twice, and is preferably approximately one and a half times, the width of the envelope tube cross–section. Alternatively the helically coiled part of the tube can be in the form of a two–start helix, with the turns of the two helical elements evenly interleaved and connected together at one end of the helix, and with the pitch of each helical –element not more than four times, and preferably approximately three times, the width of the envelope tube cross–section. The diameter of the helix into which the envelope tube is coiled can be less than one half of the axial length of the helix. The discharge envelope can be sealed within an evacuated singlewalled outer jacket or mounted within a double–walled outer jacket, either of the kind in which. the envelope is sealed within the outer jacket with the space between the envelope and the inner wall of the jacket evacuated, or of the kind. in which the envelope is detachably mounted within an evacuated outer jacket with air present in the space between the envelope and the inner wall of the jacket. In the construction shown in the drawings the ends of the envelope 1 containing the electrodes 2 extend outwards from each other parallel to the axis of the helix and project through closely fitting holes in a pair of flexible discs 11, 12, e.g. of mica, which fit closely against the inner surface of the outer jacket 3, Fig. 1, or of a hollow cylindrical sleeve 19, Fig. 2, of transparent heat–insulating material, such as glass, interposed between the envelope 1 and the jacket 3. If desired the envelope at one end of the helix can be extended back along the middle of the helix so that the ends of the envelope are located at the same end of the helix. With 'a two–start helical envelope the ends of the envelope can also be located at the same end. The disc 11, Fig. 1, is held in position by a support wire 18 welded to one of the lead–in wires 6. The protruding ends of the electrode leads 7 at the foot–tube end of the envelope are bent radially outwards and connected to the turned–out end of the lead–in wire 6, by a welded metal sleeve 13. At the other end of the.envelope the electrode leads 7 are connected by a metal sleeve 15 to a wire 14 extending along the middle of the helix within a glass capillary tube, the opposite end of the wire being connected to the other lead–in wire 6. The evacuated space within the jacket 3 contains a getter element which may be spotwelded to one of the lead–in wires 6 and provides a coating of getter material on the internal wall of the jacket near the foot–tube 5. In the construction shown in Fig. 2 the cylindrical glass sleeve 19 is held in position by additional mica discs 20, 21, the disc 20 being supported by the lead–in wire 6 which urges the disc 20 against the end of the sleeve 19 and thus the Other end of the sleeve against the other disc 21. Transverse movement of the sleeve 19 is prevented at each end by a pair of wires 22 of approximately U–shape extending into the sleeve through holes in the discs. The ends of the wires 22 also bear against the discs 11 and 12. A getter element is provided within the evacuated jacket 3. The envelope can be constructed as a unit for detachable insertion within a double–walled Dewar jacket and can incorporate an insulating support member rigidly connected to one end of the envelope, the support member carrying input terminals and being shaped to fit within the central hole in an annular base member sealed to the open mouth of the Dewar jacket. The filling can be neon containing 0.8% by volume of argon at a total pressure of about 10 mms. together with about 2 grs. of sodium. The envelope is coated internally with a layer of sodium resistant glass.

Abstract:
Source: US3848665A A slide for hot blast slide dampers having a pair of spiral volutes arranged in the shape of a flat disc having an inlet connection and an outlet connection for a coolant at the edge thereof. One of the spiral volutes leads the coolant from the inlet connection to the center of the disc and into the other spiral volute whereby the coolant is lead from the center of the disc to the outlet connection. The volutes are separated from each other by walls extending transverse to the major plane of the disc to form a cooling channel. The volutes are separated by a single common wall extending substantially perpendicular to the major plane of the disc and the cross section of the cooling channel may be substantially quadrangular. The volutes are made from spirally interwound open sections welded together.

Abstract:
Source: US4863567A The invention is a fluid distillation apparatus (10) which, in its preferred embodiment, includes a cylindrical portion (12) which mates with an end wall (14) and a bell portion (16) to form an enclosed volume (18) within which evaporization and condensation of a selected fluid may take place. A heat exchange rotor assembly (20) is formed of head conductive material and includes intertwined evaporization and condensation channels (52, 54) in spiral array. A central tunnel (58) provides access for vapor from an evaporization volume (24) to a condensation volume (26) with a pressure gradient provided by an impeller (100) urging such passage. A drum motor (68) rotates the drum (40) to facilitate liquid flow in the heat exchange rotor (20). An impure fluid input port (32) and output ports are provided for purified fluid (34), concentrated brine (36) and degassing purposes (38). The apparatus is a flow process device and is especially adapted for continuous purification, such as water distillation or desalinization.

Abstract:
Source: US2012140967A The hearing device comprises an ear–piece (1) which is designed to be worn at least partially in an ear canal of a user of the hearing device. The ear–piece (1) comprises a vent passage (3) connecting the ear canal with the atmosphere. The vent passage (3) has an inner opening (8) towards the ear–canal and an outer opening (9) towards the atmosphere. The ear–piece (1) further comprises a vent extension (4). The vent extension (4) is a protrusion extending the vent passage (3) beyond the body (2) of the ear–piece (1). The vent extension (4) is adapted for abutting on a surface of the body of the user and is thereby inconspicuous and/or contributes thereby to retention. A method for manufacturing such a hearing device is also disclosed.

Abstract:
Source: US2002062148A The disclosed stent is formed of an elongate, flexible duct having a very thin wall and a preformed diameter, length, and shape. The stent is constructed of a woven tubular structure of multiple strands or elements. The woven tubular structure is thermally set to a predetermined diameter and length, so that the "at rest" or natural condition of the tubular structure is predictable. A retention or holding member can be formed at one or both of the ends of the stent. This retention member can be reduced in diameter for insertion into the body passage. The woven tubular structure provides a path for fluids to flow in and around the stent, while a patent lumen is being developed. The woven tubular structure allows the stent to be extended or stretched over a guidewire or other noncompressive member, to thereby reduce the diameter of the stent for insertion of the stent into a body passage.

Abstract:
Source: US2002125325A A high speed non−contact beam scanning device sized and shaped to provide the ergonomic benefits of a pen or wand, yet can scan a wide angle moving beam across an information−bearing target in one or two dimensional scan patterns such as lines, rasters or other patterns in order to read information therefrom. The device is well suited for reading one or two dimensional bar−code or other printed matter. In order to achieve the high density optical packaging necessary for its high performance to size benefits the device employs a novel in−line or "axial" gyrating, or "axial" scan element. The axial scan element can accept an input light beam at one end and cause it to emerge from its opposite end as a scanned beam, propagating in the same general forward direction it had upon entering the element. Reflected light, which carries information contained on the target, is collected by an internal non−imaging light collector and is processed by signal processing electronics. All components are integrated into a thin low mass module small enough to fit in a pen. Communication from the device is achievable by a cable or by wireless means.

Abstract:
Source: US6258115B A stent comprising varying porosity's for use in vessels with bifurcations or side branches. The stent allows for scaffolding of the stenotic area but still allows for flow into the side branches. A distal protection system is also described.

Abstract:
Source: US2014153768A An earpiece designed to fit a substantial majority (over 90 percent) of people without customization to the outer ears, i.e., without the need to make customized measurements or a mold of the actual ear of an individual. The device is generally C–shaped and contacts the outer ear in four locations.

Abstract:
An apparatus is disclosed comprising a first device (1) for generating aerosol, smoke or vapour (5) from one or more regions of a target, an inlet conduit to an ion analyser or mass spectrometer,the inlet conduit having an inlet through which the aerosol, smoke or vapour (5) passes, and a Venturi pump arrangement arranged and adapted to direct the aerosol, smoke or vapour5towards the inlet.

Abstract:
Source: US2008086854A The present invention relates to a one−step fastening device, a process for creating a fastener utilizing such a device, and the end fastener produced thereby. In this regard, the invention uses an outer, hollow fastener material that can be partially compressed under tension at designated areas (i.e., a compression member) and an inner activation or tensioning member. The compression of the outer fastener material occurs at one or more flexible areas or compression features specifically located on the longitudinal axis of the material. As a result, the outer compression member is capable of being distorted or bent under tension to produce a predetermined configuration. The device described herein has the ability to form specific and controllable fasteners of designated shapes and configurations. Methods for fastening, snaring, gripping, cutting, and manipulating material using the device in a confined space are also provided.

Abstract:
Source: US4173445A In plastics extrusion apparatus including a rotating screw in a cylinder forming a channel receiving solid material and eventually expressing it through a die, the channel comprising a feed zone, a melting and compression zone and a melt pumping zone, the improvement wherein a solids decompression zone is between the feed and the melting and compression zones which has increased unit volume relative to that of the feed zone, with the channel of the melting and compression zone communicating with the feed inlet through the

decompression and feed zones such that solids are initially metered producing a starved condition so as to melt at substantially atmospheric pressure without filling the channel of the melting and compression zone until close to its end.

Abstract:
Source: US2003181827A A bi−directional steerable guidewire having a deflectable distal tip which comprises a longitudinal hypotube and a spring coil attached to the distal end of the hypotube and also includes a longitudinally movable deflection member which is attached to the distal end of the spring coil and a tip retaining member which extends from the distal end of the hypotube to the distal end of the spring coil for providing very precise deflection of the distal tip.

Abstract:
Source: US2010044252A The invention is a dehydrating and reclosable hinged plug–lid that includes a dehydrating agent, a fixation mechanical system provided between the occlusion element and the open end of the tubular container, a tamper indicator, a compensation device for preserving the conditioned products provided inside the occlusion element and secured to said occlusion element, wherein said compensation device consists of a hollow device having an essentially conical, frusto–conical, polyhedral, frusto–polyhedral apparent shape with a large annular base and a small annular base parallel to the large base, the small base in contact with the conditioned products being coaxial and connected to the large base by at least one linking element that can be deformed under the action of a mechanical pressure and that can recover its initial shape when said pressure is

no longer applied.

Abstract:
Source: US2005085915A The present invention seeks to provide improved joint implants and methods relating to joint implantation.

Abstract:
Source: US3854906A A venting and aerating arrangement for closed flow systems for water of fluctuating temperature is disclosed. A vent casing, defining an air collecting chamber, extends upwardly from a horizontal conduit of the system. A float controlled vent valve is arranged in the upper portion of the casing. A grid of spaced rods is arranged in the junction between casing and conduit and extends into the flow passage of the conduit to break up bubbles of air and other gases with the liberated gas ascending into the air collecting chamber. An improved valve construction is also disclosed.

Abstract:
Source: US4787846A The invention relates to a device for shutting off suction generated through the single tubes of dental surgery equipment, which comprises a rotary mechanical obturator (5) located in the grip (1) of the suction tube (2) and attached to a pin (3) that engages in a helical groove (6) offered by the holder (4) in which the grip is replaced whenever the tube is not in use. Pin and obturator rotate as one between an open position and a closed position, the obturator being biased permanently toward the open position by a coil spring (7).

Abstract:
Source: US2757582A 740,588. Centrifugal separators. FREEMAN, H., and BOADWAY, J. D. Aug. 27, 1953 [Sept. 24, 1952; Dec. 6, 1952; Dec. 6, 1952; Jan. 13, 1953; Jan. 13, 1953], No. 23717/53. Class 23. Solids and gases are removed from liquids in a process in which a non−rotary separator is operated so that a liquid−free core is formed, gas being evacuated from the core to maintain subatmospheric pressure in the core. Fig. 1 shows a separator suitable for purifying paper pulp and comprising a convergent inlet 11 directing the pulp tangentially into a separating chamber 10, an outlet 21 for purified pulp and some gas connected to suction means, an outlet 18 for gas connected to suction means and an outlet 20 for solids separated from the pulp. In the modification shown in Fig. 12 the purified pulp and separated solids are discharged under pressure so that gas is only evacuated by suction means. As the separated solids pass a gas outlet 107 into a chamber 123 some of their kinetic energy is converted into pressure energy so that they are discharged at pressure through the outlet 111. The purified pulp and some of the separated gas pass upwardly through the outlet 115 to a chamber 120, some of the kinetic energy of the pulp being converted into potential energy before discharge through a divergent outlet 121 and the gas being discharged through an outlet 108. In a further modification, Fig. 14 (not shown), the gas is discharged from both ends of the separator, the pulp to be separated first passing through a disclike chamber before entering a cylindrical separating chamber and the pulp and separated solids being discharged from the end of the separator remote from the inlet by means of two disc−like chambers having tangential outlets. In the modification shown in Fig. 16 all the separated gas is evacuated through an outlet 158 adjacent the inlet 151, and the pulp and solids are removed from the separator from the end remote from the inlet, the outlet for pulp being connected to a suction pipe 166 and the separated solids being discharged through a pipe 164. In a modification of the construction shown in Fig. 16 a body is centrally placed in the separator adjacent the outlet 164, to prevent gas entraining with the separated pulp. In a modification, Fig. 19 (not shown), the separator comprises a hydro−cyclone having the tapering part discharging into a vacuum chamber, the purified pulp discharging through a concentric outlet adjacent the inlet, and the separated solids and gas discharging into the vacuum chamber from which they are separately removed. In the plant shown in Fig. 2 pulp, at about 100? F., from a pipe 31 first passes through a separator 10a similar to that shown in Fig. 1, the purified pulp and separated gas from the separator 10a being directed to a separator 33 which separates the gas from the purified pulp and is as shown in Fig. 8. The gas outlet of the separator 33 is connected by pipes 34, 35, 36 to a vacuum pump 37. Cold water is supplied at 41 to condense any vapour present in the gas, the condensed vapour falling through a pipe 42 and a further pipe 43 which is over 32 feet long and into the top of which gas from the separator 10a is discharged. The purified pulp from the separator 33 is discharged into the head box 40 of a paper making machine by means of a pipe 38 over 32 feet long. The pulp discharged from the separator 10a with the separated solids is separated in a hydrocyclone 80 and discharged into the headbox. Up to 90 per cent of the gas is usually separated from the pulp. In modifications of the plant shown in Fig. 2, any of the modification of the hydro−cyclone shown in Fig. 1 may be used for the separator 10a. In the separator 33, Fig. 8, the tapering lower part of the separator and the inclination of the tangential pulp inlet 32 are so shaped and arranged that the inner parts of the layer of pulp in the lower part of the separator tend to move upwardly and the outer parts of the layer tend to move downwardly. The separated gas is withdrawn through the outlet pipe 34 connected to the suction means, and the pulp free of gas is withdrawn

by the suction pipe 38. Dimensions and performance figures for the apparatus are given in the Specification.

Abstract:
Source: US2005217667A A multipurpose aerosol medication delivery apparatus that includes a

collapsible/expandable, or a fixed volume, or a combination of partially fixed volume and partially collapsible/expandable holding chamber for use with a metered dosed inhaler (MDI) and/or any standard small volume nebulizer. The holding chamber is designed to deliver−aerosol medication particles generated by an MDI; aerosol medication particles generated by a nebulizer; a single gas or a mixture of gases; a single gas or a mixture of gases that can yield a gas density that will enhance aerosol delivery of medication with both MDI and nebulizer; a single gas or a mixture of gases that will yield and deliver an oxygen concentration to a patient ranging from room air concentration to 100 percent. The device includes a reservoir that stores nebulized aerosol generated during exhalation to be inhaled during the next breath. The device also included a one way valve to prevent carbon dioxide generated during exhalation from rebreathing by not allowing the exhaled air from entering the holding chamber. The device includes an exit port with a second one way valve that allows the exhaled air to exit the device but closes during inhalation to prevent any entrainment of room air gas. The exit port may instead have a filter with one−way valve to trap the exhaled aerosol particles while allowing the exhaled gases to escape. The filter valve will similarly close during inhalation to prevent entrainment of room air gas. The holding chamber will allow a uniform mixture of aerosol medication and gases to flow together during inhalation to the patient via a mouthpiece or a facemask. The holding chamber is connected to a nebulizer chamber with a single or multiple connecting tubes that allow gas mixtures with varying density, viscosity, humidity and concentration of oxygen to flow into the holding chamber from the nebulizer chamber. The pattern of flow of the gas(es) does not disturb the flow of the nebulized medication from the nebulizer chamber to the holding chamber or interfere with the plume generated by an MDI. The device also serves as a facemask for delivering precise concentrations of oxygen or as a 100 percent non−rebreather mask. The device also serves to deliver precise concentrations of different density gases i.e. nitrogen, helium, oxygen, etc. This will allow varying fractions of inspired oxygen to deliver aerosol medication via MDI or a nebulizer. Thus, the device has the ability to deliver aerosol medication with an MDI or a nebulizer while retaining the ability to simultaneously deliver different density gas mixtures and varying fraction of inspired oxygen without interrupting one for the other.

Abstract:
Source: US5243988A A device for ultrasonic imaging, and methods for the use an manufacture thereof, particularly of small coronary vessels. The device comprises an elongate member with a distal end that can be positioned within a small vessel of a patient's body while a proximal end is located outside the body, a transducer located at a distal end of the elongate member and operable to scan the distal coronary vessels with ultrasonic pulses, and a signal processor connected to a proximal end of the elongate member and to the transducer for generating and receiving pulses to and from the transducer. A motor may be also connected to the proximal end of the elongate member for rotating the transducer.

Abstract:
Source: US2013226289A Apparatus, systems, and methods are provided for repairing heart valves through percutaneous transcatheter delivery and fixation of annuloplasty rings to heart valves. An annuloplasty ring includes an outer hollow body member including a plurality of regions. Adjacent regions cooperate with one another to change the body member from an elongate insertion geometry to an annular operable geometry. Adjacent regions are coupled by a biasing element or a stepped connector to allow expansion to an expanded state and contraction to a contracted state in the annular operable geometry. The annuloplasty ring also includes an internal anchor member located at least partially within the body member and having a plurality of anchors configured to attach the annuloplasty ring to tissue of a heart valve annulus. An angled ring closure lock allows coupling of the ends of an annuloplasty ring at an apex of a D−shape annular operable geometry.

Abstract:
Source: US5186713A A method, device and system for providing a flow of oxygenated perfusion fluid (e.g. oxygenated whole blood) through a balloon angioplasty catheter to perfuse tissues which would normally be deprived of blood flow when the balloon of the angioplasty catheter is inflated. In accordance with the invention, an extracorporeal membrane oxygenation device is fluidly connected to the angioplasty catheter such that oxygenated fluid (e.g. oxygenated whole blood) may be passed through the catheter and caused to exit the catheter distal to the angioplasty balloon. The patient's own blood may be withdrawn, oxygenated by the extracorporeal membrane oxygenation device and subsequently reinfused through the angioplasty catheter. A dual–lumen introducer sheath may be employed for the dual function of a) facilitating insertion of the catheter and b) allowing withdrawal of blood for subsequent oxygenation and reinfusion through the angioplasty catheter.

Abstract:
Source: US5752825A An endodontic system of shaping instruments, irrigation cannulas, filling instruments and materials designed to safely create specific tapers of root canal preparations and to clean, dry, seal, and restore them. The shaping instruments are a series of reamers, files, and handpiece burs, made of stainless steel,

nickel–titanium, or other alloys, which impart several different specifically–tapered apertures in root canals. The instruments have one or more safety features to eliminate perforating curved roots, including shorter flute length as the angle of taper increases and variable sharpness along the length of the flute portion, as well as variable flute pitch along the length of the flute portion to maximize cutting efficiency and resistance to breakage, and a rounded tip to eliminate ledging. The hand instruments have a handle designed to optimize use of the instruments in apically directed, rotary cutting motions. The irrigation cannulas, the condensation heat carriers, pluggers, injection needles, and backfillers, and the materials, including drying paper points, filling materials, and restorative post systems, have shapes which match the canal tapers created by the shaping instruments.

Abstract:
Source: US2006217697A A surgical apparatus and methods for severing and welding tissue, in particular blood vessels. The apparatus includes an elongated shaft having a pair of relatively movable jaws at a distal end

thereof. A first heating element on one of the jaws is adapted to heat up to a first temperature and form a welded region within the tissue, while a second heating element on one of the jaws is adapted to heat up to a second temperature and sever the tissue within the welded region. The first and second heating elements may be provided on the same or opposite jaws. A control handle provided on the proximal end of the elongated shaft includes controls for opening and closing the jaws, and may include an actuator for sending current through the first and second heating elements. The first and second heating elements may be electrically connected in series, and the first heating element may be bifurcated such that it conducts about one half of the current as the second heating element. A force−limiting mechanism provided either within the control handle, in the elongated shaft, or at the jaws limits the pressure applied to the tissue by the jaws to ensure that the tissue is severed and the ends effectively welded within a short amount of time.

Abstract:
Source: US4943275A A balloon assembly has an intrinsic curvature adapted to a passage in a blood vessel, and is straightened by a removable stiff member extending within the catheter to facilitate insertion along the passage. When the balloon is at a curved portion of the passage, the stiff member is retracted, allowing the balloon and adjacent support to conform to the curved passage and advance further without trauma to the vessel. The curved balloon may be stably positioned in a curved arterial passage and pumped with a pulsatile inflation source.

Abstract:
Source: US2016220259A A tool is described for delivering and applying a clamping implant (9; 109) via a puncture in skin tissue (3) and underlying tissue (2) of a patient, comprising a hollow needle (4; 104) bounding a lumen (5; 105) and forming a helix, a plunger (6; 106) of which a distal portion extends in longitudinal direction inside the lumen (5; 105), and a plunger operating member (7; 107) engaging a proximal portion of the plunger (6; 106) projecting from the needle (4; 104), for screwing the plunger (6; 106) further into or out of the needle (4; 104) by screwing rotation of the needle (4; 104) relative to the plunger (6; 106). A system is also described, including such a tool, and a method is also described for delivering and applying a clamping implant (9; 109) using such an instrument.

Abstract:
Source: US5047025A A catheter is provided with a heated temperature self regulating tip for insertion in an artery to ablate an atherosclerotic plaque obstruction particularly in coronary and peripheral arteries. The heater is located at the distal end of the catheter and has a winding of fine wire around a ferro−magnetic core with the wire being connected via a transmission line to a high frequency constant alternating current source in the megahertz range. The catheter which may or may not employ a guide wire is inserted into and through the lumen of a vessel and guided usually with the assistance of fluoroscopy to the location of the stenosis. The heater is energized to ablate the plaque, the temperature not exceeding a desired temperature as determined by the Curie temperature of the ferromagnetic material.

Abstract:
Source: US2001025170A An apparatus (1) for extracting fluids from a body tissue or organ having an aperture, including a seat (26) for positioning said tissue, and a pressure means (17,22) for applying pressure to said tissue while leaving said tissue aperture open for the exit of said fluids. The surface (23) of the supporting surface of the tissue is shaped as a funnel or cone, so that the apex is directed downward and the base (29) delimits the supporting surface of the tissue; the apex region being constituted by a hollow cylinder (22) in order to allow the passage of the umbilical cord of a placenta or of the vessel for the drainage of fluids from the placenta or organ or tissue; the supporting surface being provided so as to avoid producing obstructions or collapse of the surface vessels of the placenta or organ or tissue, so as to avoid hindering the flow of blood or fluid.

Abstract:
Source: US2001025157A A compact, small−volume, very low flow rate fluid dispensing device for precisely dispensing medicinal fluids into a patient at a very low, controlled flow rate over long periods of time. The dispensing device is readily implantable into the patient's body and includes a novel heat stimulatable polymer gel material which uniquely functions as an internal energy source for controllably expelling the medicinal fluids from the device.

Abstract:
Source: US5377483A An annular combustor system is disclosed in use with a radial turbine−type gas turbine engine module, the system having an annular housing defining a single stage combustor, an external fuel/air premixer system having a mixing chamber and a compressed air valve and a fuel valve both under the control of a controller, to provide a preselected lean fuel/air ratio mixture for introduction to the combustion zone of the annular housing. Compressed air conduits are used to channel a portion of the total compressed air flow to the premixer and the remainder to the dilution zone of the combustor, and a fuel conduit is used to deliver all of the fuel to the premixer. Convection cooling of the annular housing is accomplished using compressed air without diluting the fuel air ratio in the combustion zone. The premixer includes a venturi, a fuel nozzle for spraying fuel into the venturi inlet along the venturi axis, and a premixer housing integrating the compressed air valve, the venturi axis being aligned substantially tangentially to the annular housing axis to provide a swirling admission of the premixed fuel/air mixture to the combustion zone.

Abstract:
Source: US2003164952A The invention concerns the three−dimensional scanning of interior surfaces or cavities of limited dimensions or with restricted accessibility by providing a probe−shaped non−contact adpated to perform a scan 360 degrees around the axis of the probe and a method for scanning. The invention furthermore relates to the creation of high precision three−dimensional replicas of real objects using 3−D scan data obtainable with the scanner according to the invention. Furthermore, the invention relates to a specific embodiment for scanning the human ear and ear canal.

Abstract:
Source: US2004210249A Non−expandable space−occupying devices for treating voids within the body are disclosed. The devices can have multiple non−expandable space−occupying elements connected to a flexible leader. Methods of making and using the devices are also disclosed.

Abstract:
Source: US6179809B A steerable drug delivery catheter and method of use, particularly adapted for percutaneous use. The distal end of the drug delivery catheter is deflectable. The catheter has a relative movement compensation mechanism for maintaining positioning between the distal end of the drug delivery catheter and the distal end of the drug delivery device therein.

Abstract:
Source: US3004397A (Claim 1) 1. An apparatus for dehydrating a heat sensitive liquid composition of relatively low solids content comprising a plurality of interconnected refrigerating tanks for receiving said liquid composition, said tanks including elongated stationary freezing cylinders spacedly arranged therein, said cylinders comprising a hollow outer shell wall for the passage of refrigerant, a central passageway for refrigerant communicating with said hollow outer shell, a pipe line for connecting said central passageway of one of said freezing cylinders with a source of refrigerant, conduit means for connecting said freezing cylinders of each tank in series for the passage of refrigerant through said cylinders and to a discharge line connected to the last freezing cyiinder of said series, electrically operated valve means disposed in said pipe line for alternately admitting and restricting the passage of refrigerant to said freezing cylinders and through said hollow shell walls, means operable in response to temperature changes of the refrigerant in the freezing cylinders for actuating said valve, said last–mentioned means including a thermometer bulb disposed in said discharge line of the last freezing cylinder, means for introducing the liquid composition to be dehydrated into said refrigerating tanks, electrically operated valve means operatively connected to each tank for discharging the refrigerated mixture to a centrifuge, and means comprising a common header arranged above and discharging into said centrifuge for collecting said refrigerated mixture discharged from said plurality of tanks.

Abstract:
Source: US6355051B A guidewire filter (10) has an elongate hollow tube (12) with a proximal end, a distal end, an inside, an outside surface, and a lumen formed therethrough. The hollow tube (12) has a plurality of longitudinal slots (14) forming a plurality of longitudinal rib portions (16) near the distal region of the hollow tube (12). An actuating wire (24) with a proximal end, and a distal end is provided. Filter material (20) is positioned within the

lumen in the hollow tube (12). An activation handle (38) on the proximal end of the device (10) is provided for pulling the actuating wire (24) relative to the hollow tube (12).

Abstract:
Source: US2004122366A A drug to be infused into a patient is contained in a syringe or vial having a displaceable plunger for ejecting the drug out through an injection port into an administration set. Motion of the plunger of the drug delivery syringe/vial is controlled by a driver syringe having a piston or plunger for ejecting either a compressible or an incompressible fluid through a flow resistance element. Motive power for the piston of the drive syringe is provided by a constant load spring. A suitable linkage is provided for coupling the piston of the drive syringe to the plunger of the drug delivery syringe. Several types of flow rate control elements for use with the driver syringe are disclosed.

Abstract:
Source: US5078727A A balloon dilatation catheter has a flexible, hollow inner shaft and an outer, braided shaft with a balloon that is inflatable by fluid introduced between the outer and inner shaft. The inner shaft is fixed relative to the outer shaft at both ends such that, when the balloon is inflated, the outer shaft shortens and the excess length of the inner shaft is accommodated by the inner shaft bending into a coil within the balloon.

Abstract:
Source: US5336570A Disclosed is a hydrogen fuel cell which resists swelling of a proton−exchange membrane electrolyte by clamping the membrane between two catalytic electrodes in a tubular or frusto−conical configuration. Improved breathability and hydrogen sealing are obtained. The electrodes can be bonded to the solid electrolyte by employing an electrolytic proton−transporting polymer in the liquid−phase. Including finely divided platinum in the liquid phase provides an advantageous means of incorporating catalyst in the cell. Also disclosed is a blind tube porous carbon electrode assembly which can be manufactured by a method including coating a self−supporting electrode with a liquid−phase polymeric electrolyte material, for example, perfuorosulfonic acid, and curing it.

Abstract:
A method and device (10) resolve occlusive deposits in a tubular passage of a subject by radio frequency ablation. The device (10) has a distal end (20) which is inserted within, along the lumen of a tubular body member, and may be manipulated therethrough to a desired position where the device will be operated. The device (10) includes an elongated flexible hollow tube (12) having a distal end, a proximal end, and a diameter smaller than the diameter of the tubular body member into which the device is being inserted. A number of electrodes (14) adjacent the distal end of the device, capability for selectively supplying radio frequency electrical current to at least one of said electrodes (14), and capability such as an inflatable balloon (30) for radially positioning the electrodes (14) with respect to the tube. Another embodiment includes electrodes (14) at varying radial positions so that at least one of such electrodes (14) will be capable of ablating material at varying positions within the lumen.

Abstract:
Source: US2008194939A Apparutus and methods are described for performing percutancous catheter−based interventional surgery. The apparatus comprises first and second devices that are located in adjacent body cavities, such as adjacent blood vessels, the first device being capable of transmitting a directional signal that can be received by the second device. The direction of the signal is correlated with the facility to direct therapy, such that improved accuracy in therapy placement is thereby achieved. Methods for treating patients utilising the means and apparatus are also provided.

Abstract:
Source: GB1262955A 1,262,955. Measuring blood pressure. WALTER BECK K.G. KONTROLL–UND FERNMESSGERATE. 28 March, 1969 [1 April, 1968], No. 16533/69. Heading A5K. A blood pressure measuring instrument comprises a cylindrical handle 1 containing an air pump 6 connected through a non–return valve 17 to an occluding cuff 25 and an air release valve 62 actuated by an operating ring 71, a pressure responsive chamber 32 in communication with cuff 25, which, through a lever system 35, 40, 42 actuates a pointer 41 moving over a scale plate 54. The handle 1 comprises a core member 3, having a recess 4, on which there is fitted a hood 5 of elastic material incorporating integrally the pump 6 and a non–return inlet valve 12 therefor. The edge 7 of the hood is sealed by a cover ring 10 against the top portion 8 of core member 3. A middle part 26 is attached by a bayonet fixing 27, 28 to the top portion 8 against a sealing ring 29 to define a chamber 19, which connects with non–return valve 17 and a bore 21 in communication with the occluding cuff 25, the chamber 19 having a central bore 30 into which the pressure responsive chamber 32 is screwed. An air escape hole 61 extends radially from bore 30 into a radial bore 60 of larger diameter containing a push rod 64. Operating ring 71 has an inwardly projecting rib 73 which provides an eccentric surface (75, Fig. 5) which acts against the curved head (74, Fig. 4) of the push rod to force a cylindrical sealing part 62 of elastic material over the end of hole 61 and into a channel (76, Fig. 3) in the end wall of bore 30. In the operation of the device, the handle 1 is gripped by the user and the bellows operated with the fingers to inflate the cuff 25. The operating ring 71 is then turned until the sealing part 62 detaches from channel 76 and allows air to bleed off slowly. The chamber 32 carries on a threaded pin 33 a ring 34 which actuates arm 36 of an angle lever 35, whose other arm 38 has a hook 39 engaging a shackle of a chain 40, the other end of which is fixed to a shaft 42 carrying pointer 41 and a spiral return spring 43. The sensistivity of the instrument may be adjusted by moving ring 34 along the axis of pin 33, and by moving the angle lever mounting pin 53, which is mounted in a bow 51 attached to a leaf spring (48, Fig. 6), whose position may be altered by turning a screw (50, Fig. 6). An alternative arrangement is shown on Fig. 7. The instrument may include a means of indicating periods of time (91, Fig. 2) and a mechanism (Fig. 2) enabling it to be wound up by turning operating ring 71, as described in Specification 1,262,954.

Abstract:
The invention relates to a medical device for treating body vessels, particularly blood vessels or other tubular structures in the body, especially the urethra, trachea, and esophagus. Said medical device comprises a first, proximal sealing unit (3) and a second, distal sealing unit (4). The first sealing unit (3) is offset from the second sealing unit (4) in the longitudinal direction of the body vessel (13) when being inserted therein so as to create a separate treatment space (10). A duct which is disposed between the first sealing unit (3) and the second sealing unit (4) connects the space upstream from the first sealing unit (3) to the space downstream from the second sealing unit (4) in order to allow fluid to flow in the body vessel while the device is in use. The wall of the duct can be configured in a flexible manner such that the surrounding conditions can be transferred to the treatment space. A vessel dressing can be created or holes in the vessel wall can be repaired by introducing natural cells or a mixture of natural cells and a natural and/or artificial polymer, particularly fibrin or collagen, into the treatment space. The inside of the duct of the inventive device can be provided with form elements or a valve–type arrangement such that the device can replace degenerated venous valves as an implant. The inventive device can also be provided with hollow form elements which are connected to the treatment space such that a matrix is formed for creating venous valves made of natural cells when natural cells or a mixture of a polymer and natural cells is/are introduced into the treatment space.

Abstract:
Source: US2017120001A A self–slitting open lumen cannula may be used with catheter adapters to reduce manufacturing complexity and costs, as well as improve the safety of the catheter adapters against fluid leakage. The open lumen cannula may also include one or more notches to facilitate flashback visualization. The catheter adapters may further include a catheter adapter body formed of a compliant material that houses one or more compression resistant septa with at least one lumen formed by the proximal end of the needle during a self–slitting process as the catheter adapter is assembled. The compression resistant septum may also be coupled to a compression cap that imparts a radial compression force on the one or more compression resistant septa such that the at least one lumen narrows and seals when the cannula is removed.

Abstract:
Source: US2014148673A A catheter comprises a flexible polymer catheter body including a proximal shaft section and a distal working section, a wire support structure embedded within the distal working section of the catheter body, a proximal adapter mounted to the proximal shaft section of the catheter body, and a wire disposed within the catheter body. The wire has a proximal end and a distal end. The proximal end of the wire being operably connected to the proximal adapter, and the distal end of the wire is anchored to the wire support structure.

Abstract:
Source: US2017095624A Devices and methods are described for preparing, managing, and/or administering metered doses of substances for vaporized administration. In some embodiments, dose cartridges comprising at least one botanical substance include a heating element integrated into the cartridge in close contact with the botanical substance. In some embodiments, cartridge–mounted doses are stored in a magazine, optionally in carousel form, before use. Transport of a cartridge from a magazine to an electrically operated vaporizing chamber which activates the heating element is provided by a mechanical pickup means.

Abstract:
Source: US6432117B A probe element with helical grooves is dimensioned to be inserted into the ear canal and stop short of the ear drum, the element being made of soft compressed cotton. A bulbous flexible plastic handle has an interior rod and a clutch for releasably receiving the element. Depressing the handle at the rod location forming an ejection button displaces the rod and an interior–coupling member for ejecting the probe element. The rigid smooth handle is rotated a quarter turn to remove wax from the ear canal. The element extends from the handle a predetermined length to not engage the eardrum, the handle having a blunt tip acting as a stop for the element during insertion.

Abstract:
Source: GB413764A 2941 and 6007. [Class 146 (iii).] A self filling stylograph pen is provided with a solid writingpoint associated with a feed–bar, air–channels being provided in either or both the feedbar and the surrounding pointsection, and inkchannels being formed on or in the point and completed, if necessary, by other channels in the feed–bar. The point is of the type described in Specification 364,808, and consists of a member divided longitudinally into separate parts or of a number of separate elements such as wires, grouped together to form capillary channels, rounded and polished at the writing–end, and connected together for a portion of their length by soldering or other means to control the rigidity ; the point may be surrounded by a tube which may conform to the contour of the elements, and the tube may be formed with one or more internal constrictions or projections to control the flow of ink. The point e, Fig. 2, is preferably secured in position in an axial passage in the feed–bar d, but may be yieldingly mounted to facilitate movement of the tip over the surface. The feed–bar need not completely surround the point, but may be in the form of wings or projections at the forward end. Means may be provided for preventing inward movement of the point, and for preventing closing of the feed–passage in case the feed–bar is formed of insufficiently rigid material. The passage in the feed–bar may be continued directly through a passage c<1> in the point–section c into communication with the collapsable–sac reservoir b, or may be connected with the passage c<1> by means of a radial passage f<3> and a longitudinal spiral, or tortuous groove f<2> formed in, or in association with, the feed–bar. The bottom of the ink–feed channels may be grooved to facilitate flow, and the flow may be controlled by means of slots extending from the rear end of the feed–bar into communication with the point, the slots overlapping for a part of their length on being arranged at an angle to each other. Local reservoirs for ink may be formed in the feed–bar or point–section. The flow may also be regulated by the provision of a siphon arrangement either in the reservoir or in the passages formed in the feed–bar, or by the provision of a short length of tube adjustable on the point. An air passage f on the feed–bar may communicate directly with the reservoir through the passage c or through an air–tube g, g<1> arranged centrally or otherwise in the sac. The air–tube extends nearly to the rear end of the sac to facilitate filling, and is formed of soft rubber so as not to interfere with the action of the self–filling mechanism. The feed–bar may be provided with a coned rear end d<6>, Fig. 42, which on application of a cap s is forced against the action of a spring t, to close the ink–feed aperture c<1>. Alternatively, grooves may be formed in the point section and feed–bar to overlap for a small part of their length, so that relative rotation or longitudinal movement of the point–section and feed–bar will interrupt the communication and stop the flow of ink. According to one of the Provisional Specifications, the point may be formed of a piece of fluted wire or metal strip and wires or strips may be laid in the grooves, or the point may be made from a metal tube slit and bent inwardly at the free end to form a rounded tip with an interval feed–channel.

Abstract:
Source: US2003120291A Forming a proximal anastomosis on an aortic wall includes method and instrumentation and apparatus for forming an aortic puncture and inserting a fluid−impervious sealing element with a lateral flange and central stem into the vessel through the puncture. An anastomosis of a graft vessel over the puncture is partially completed with the central stem of the sealing element protruding through the partial anastomosis. A removal instrument attaches to the central stem and retrieves the sealing element that disassembles in helical disassociation of the flange and stem into a continuous strand that is withdrawn from the partial anastomosis prior to completion of the procedure.

Abstract:
Source: US5041084A A single stage catheter which is used in open heart surgery to by–pass blood from the heart to a life support machine. The single stage catheter has a spiral lead flute for insertion into the inferior vena cava of the heart and a root section with multiple openings to be positioned in the right atrium of the heart. The

flutes of the spiral lead to small quadrant openings in the end of the root section which also has long and short axial slot openings leading to the interior of the catheter. An obturator is designed to block the long and short axial slots during insertion to allow flow only through the quadrant openings to the interior of the obturator.

Abstract:
Source: US4985022A An epidural catheter is disclosed having a durable and a flexible segment joined together. The flexible segment is inserted into a patient with the use of a well−known needle which is removed by passing the needle over the outside of the catheter. The flexible segment is atraumatic to the surrounding tissue. The flexible segment includes a plastic tube surrounded by a wire coil for pushing the tube into a passageway of the tissue. The distal end of the plastic tube and wire coil are joined to prevent unwinding of the coil when extracted. The tightly coupled wire coil also permits the flexible portion to be easily inserted into the passageway of the tissue. The durable segment joined to the flexible segment includes a stainless steel tube with a flat wire coil surrounding a length of the tube. The stainless steel tube permits fluid at an elevated pressure to pass through the hollow passageway therein without rupturing. The flat wire coil prevents kinking of the semi−rigid stainless steel tube. When a fluid at an elevated pressure is received, the distal end of the flexible tube is closed to diffuse the fluid passing through the length of the catheter. Slits are provided laterally on the side of the plastic tube for emitting and diffusing the fluid through the wire coil.

Abstract:
Source: US4472004A A bearing assembly for supporting the shaft of a spinning rotor is provided having a housing in which a pair of roller bearings are mounted spaced from each other along the shaft and which journal the shaft. Interposed between the roller bearings and surrounding the shaft is a sleeve in the form of a tubular member provided with at least one capillary channel formed between the inner and outer surfaces and extending

longitudinally between its frontal ends. At least one hole extends from the outer surface radially inward in communication with the capillary channel. In this manner lubricant supplied to the housing exterior of the sleeve will pass through the hole and the capillary channel into direct contact with the roller bearings.

Abstract:
Source: US2011208089A A biopsy device includes coaxially disposed inner and outer needles in which the outer needle tip is configured for obtaining a tissue sample. The inner surface of the outer needle includes a tissue retention feature which may include a countersink and/or a feature formed in the inner surface. The device may be configured such that the inner needle does not extend past a certain point within the outer needle.

Abstract:
Source: US2004059304A A device for the drainage of the bladder through the body's own urethra opening outside of the human body, comprising a tube−shaped body (10). The tube−shaped body is comprised: to assume a first contracted position and for taken up within the bladder as well as a to assume a second partially extended position. At least one thread (14) extends between the bladder and an opening of the urethra and is attached at a first end of the tube−shaped body so that the tube−shaped body can be extended from the first position to the second position during the application of a pulling force upon the thread. The tube−shaped body in the second partially extended position extends in such a manner so as to exceed the distance between the bladder and the point of the urethra's closing. The tube−shaped body is comprised in such a manner that it will return to the first position upon the release of the pulling force on the thread. The device is inserted into the bladder, in that a tube−shaped body is extended and inserted into an extended tube−shaped introducing member. The introducing member is inserted in through the urethra, so that the end piece of the tube−shaped body enters the bladder. The tube−shaped body is pushed out of the tube−shaped introducing member and into the bladder during the course of which it returns to the first contracted position completely within the bladder and in the course of which the placement of a thread that is attached to the tube−shaped body and that extends outside of the urethra is left to remain.

Abstract:
Source: US4768507A This invention is in the field of percutaneous insertion catheters that are used for placing a coil spring stent into a vessel of a living body for the purposes of enhancing luminal dilation, preventing arterial restenosis and preventing vessel blockage resulting from intimal dissection following balloon and other methods of angioplasty. The stent can also be used for the maintaining patency of many different ducts or vessels within a living body.

Abstract:
Source: US4655938A A process and apparatus for the regeneration in operation of lubricating oils having a first stage in which a flow of oil passes through a filtering surface, then a second and third stage in which a portion of the flow of oil is intercepted and sent countercurrently under a pre−established overpressure to the first stage flow and finally, a fourth stage for varying the position of delivery countercurrent to the filtering surface.

Abstract:
Source: US2001051801A A cryogenic catheter includes an outer flexible member having at least one cryogenic fluid path through the flexible member. The at least one fluid path is defined by a plurality of flexible members disposed within the outer flexible member.

Abstract:
Source: US2001016675A The device and method for reducing heart wall stress. The device can be one which reduces wall stress throughout the cardiac cycle or only a portion of the cardiac cycle. The device can be configured to begin to engage, to reduce wall stress during diastolic filling, or begin to engage to reduce wall stress during systolic contraction. Furthermore, the device can be configured to include at least two elements, one of which engages full cycle and the other which engages only during a portion of the cardiac cycle.

Abstract:
Source: US2012323253A A device for positioning an electrode in tissue includes: a lead body having a distal portion; an electrode array coupled to the lead distal portion; an anchoring element having an anchor tip and being operable in a first configuration in which the anchor tip is retracted within the lead and in a second configuration in which the anchor tip is extended outside the lead and configured to fixate within the tissue; and a displacement mechanism that is actuated to bias the electrode array or the anchoring element toward the tissue. A method for positioning an electrode in tissue includes: navigating, to the tissue, a lead with an electrode array, an anchoring element with a distal anchor tip, and a displacement mechanism; biasing the electrode array and anchoring element towards the tissue with the displacement mechanism; and deploying the anchoring element, and verifying fixation of the anchor tip within the tissue.

Abstract:
Source: US20163368l3A Described herein are devices, systems, and methods for wireless power transfer utilizing a midfield source and implant. In one variation, a midfield source may be realized by a patterned metal plate composed of one of more subwavelength structures. These midfield sources may manipulate evanescent fields outside a material (e.g., tissue) to excite and control propagating fields inside the material (e.g., tissue) and thereby generate spatially confined and adaptive energy transport in the material (e.g., tissue). The energy may be received by an implanted device, which may be configured for one or more functions such as stimulation, sensing, or drug delivery.

Abstract:
Source: DE19622184A1 The device has a blood pump (1) which pumps the perfusion fluid e.g. blood from a large circuit with organ containers for the organs to be perfused, into a small circuit with an oxygenator (6) for gas exchange. The blood pump (1) also pumps back from the small circuit to the large circuit. The device also includes an easily exchangeable, blood conveying, re–usable organ container (OHB). The organs which replace the natural organs e.g. the heart, lungs, kidney and liver, such as the blood pump (1), oxygenator (6), dialyser (7) and liver substitute organ (10) all have small dimensions and weight and are combined together into a portable device and are driven together. These artificial organs are connected together for uninterrupted ventilation with uninterrupted blood flow although the organs can be used individually or together as required. The organs are arranged for uninterrupted, optimal blood flow. To reduce the required blood pressure of the pump (1) the organs e.g. active oxygenator (6) have their own internal pump and recycling function. The surfaces over which blood pass have pores along their length. Through these pores, with high hydraulic resistance preventing the blood passing through, an active blood thickening substance is added to the blood. The flow rate of the blood in the problematic area of the artificial blood vessel wall is thus increased within strict limits. The blood pump (1) and the blood conveying parts, the separately exchangeable liver module, the battery and the computer with keyboard are easily replaceable components of the device to provide a live support perfusion function. These artificial organs (6,7,10) can also be fitted into a safe, self controlling light device in a compact housing (56).

Abstract:
Source: US2002045852A Heat transfer catheter apparatus and methods of making and using same are disclosed wherein fluid connection means is provided between the distal portions of two adjacent, thin−walled, high strength fluid lumens to define a closed loop fluid circulation system capable of controlled delivery of thermal energy to or withdrawal of thermal energy from remote internal body locations.

Abstract:
Source: US2006253184A The present invention provides a delivery mechanism for percutaneously routing a stent or graft through the vascular system and procedures for addressing an aneurysm or an otherwise damaged vessel. The delivery system includes an outer tubular guide catheter 20, an inner tubular delivery (pusher) catheter 14 coaxially disposed and slidable relative to the outer guide catheter and an elongated flexible wire or cable 26 that is coaxially insertable through the lumen of the inner tubular catheter and that has a frusto−conical bead affixed at the distal end thereof which is sized to at least partially fit within the lumen of the inner pusher catheter when a proximally directed tension force is applied between the elongated flexible wire or cable 26 with respect to the pusher catheter 14. By inserting a compressed coil spring between a proximal end portion of the pusher catheter 14 and the proximal end portion of the cable 26, the requisite clamping force is maintained to secure the stent or graft to the distal end of the pusher catheter until the compression spring force is removed. With the stent or graft clamped to the distal end of the inner pusher catheter, it can be drawn within the lumen of the outer guide catheter for delivery therewith to the target site.

Abstract:
Source: US2007017527A The present invention is directed to a novel device and method for providing a disposable endotracheal intubation device for use with an auxiliary passageway serving as a guide for the placement of an orogastic or other enterally directed device in a patient. The present invention pertains to a combination intubation device comprising an endotracheal tube and a catheter proximate the endotracheal tube to guide the path of an enteral tube. In a preferred embodiment, the endotracheal tube is capable of defining an arcuate path in a first geometric plane between its proximal end and its distal end to facilitate introduction of the tube into the trachea of a patient. In a preferred embodiment, the catheter employs a fenestration to facilitate removal of the intubation device from the patient without removal of any enteral device previously directed therethrough into the patient.

Abstract:
Source: US2004044364A Surgical tissue fasteners and related deployment systems and methods are disclosed. A tissue fastener used to join multiple tissue layers includes a first member, a second member, and a connecting member connecting the first and second members. In some embodiments, the first and second members are configured to expand from a delivered state to a deployed state in which the fastener secures the tissue layers together. Other tissue fastener embodiments include means for applying a substantially constant force on the tissue layers and/or means for adjusting a length of the connecting member between the first and second members.

Abstract:
Source: US5314472A A vascular stent includes at least one filament formed into a wave−like pattern, the filament being wound into a substantially spiral shape; and a device for connecting at least one end of the filament to slide on a another portion of the filament so as to form a hoop at each end of the spiral shape.

Abstract:
Source: US5753100A An ionization delivery unit suitable for introducing microbicidal metal ions into an aqueous fluid comprises an inner cylindrical electrode surrounded by a cylindrical outer electrode disposed to provide a flow path generally shaped as a hollow cylinder, aqueous fluid introduced into the flow path by an inlet which imparts a substantial tangential component to the fluid flow. The vortexing flow encourages even electrode wear and minimizes deposition of occluding substances on the electrodes. The inner electrode is preferably a copper/silver anode while the outer electrode is preferably a stainless steel.

Abstract:
Source: GB1175434A 1,175,434. Vacuum packaging. C. PLATELL 26 July, 1967 [27 July, 1966], No. 34362/67. Heading B8C. [Also in Division E2] Bags are formed and filled successively to provide a chain of joined packages divided from each other by transverse welds but intercommunicating along the chain and open to atmosphere at one end of the chain whereby they may be vacuumized through that end and if desired, have inert gas admitted. Vacuumizing is carried out by coiling the chain under tension with an interleaving strip and placing the coil in a vacuum chamber. The chain may be formed from one doubled or two superposed webs and the transverse welds may each have a gap providing the air withdrawal passage. Alternatively, an intermittent longitudinal weld 13 spaced from one edge may provide communication with a common passage 12 between the weld and edge, the passage being retained open by a permeable cord and c. filling 11. The end of such a passage or the gap in the transverse weld at the end of the chain is closed off before the packages are exposed to atmosphere, after which the incomplete welds are rendered continuous to seal off individual packages. The packages may remain in the chain with lines of perforations between them to assist separation, or may be severed from each other. The packages are vacuumized by winding them on a drum with the interleaving strip of steel, reinforced plastics and c. The coil is then strapped and placed in the vacuum chamber which may also be an autoclave for sterilization purposes. The strip may apply pressure and may have markings to impress a pattern and c. on packages filled with granular material. It may be a hollow sealed tube enclosing sufficient air to cause it to swell under vacuum between the package coils Figs. 7,8 (not shown), and thus have a shaping function. Alternatively, pairs of pins projecting from one side of the strip may bridge the spaces between the strip coils on either side of the packages and thus relieve the latter of pressure Figs. 5, 6 (not shown). Known sealing means may be provided on the vacuuming chamber to seal the air exit from the chain, or a one way valve, e.g. a spring clip may be fitted on the end package. Several chains of packages arranged side by side may be coiled or chains as in Fig. 2, may be joined by pairs of hinged clips, Figs. 9–12 (not shown, but see Division E2) and coiled, flexible pipe connections ensuring continuity of the channel. The end of the channel may be connected within the chamber to a three way valve which is switched over to an inert gas source after vacuumizing, Fig. 14 (not shown). The final sealing and severing may be controlled by photo–electric means. The side plates of the coiling drum may be adjustable for various package widths.

Abstract:
Source: US5062145A A humidifier of small gases passageway volume (of the order of 50 ml gases space) has a heater within a water containing envelope having a microporous wall common to the water space within the envelope and the gases space, the microporous wall being permeable to water vapour but not liquid water and the envelope being reinforced by a support which also directs the flow of gases over the surface of the envelope. The heater is wound as a flat spiral to avoid the effect of gases or water vapour bubbles on heater performance temperature.

Abstract:
Source: US5555908A A valved adapter for connecting a fluid handling device to a medical device includes a body with a longitudinal axis and having a female luer fitting at a proximal end, a distal end and a passageway therethrough. The passageway has a chamber intermediate the proximal end and the distal end containing a valve having a normally closed position but operative to an open position. The valve includes a relatively elongate resilient member with a proximal end and an axis substantially coaxial to the longitudinal axis of the adapter. The valve further includes a pusher disposed at the proximal end of the elongate resilient member. The pusher includes a telescopic portion having an extended position and a collapsed position. The telescopic portion is biased to the extended position.

Abstract:
Source: US4313491A A series of tubes wound in spiral, spaced relation in pressure contact with the next inner tube or a central cylinder to form, between them, a spiral path for one liquid flowing upwardly in the space between the tubes, while another liquid flows downwardly in the tubes. The outermost tube may be enclosed by a sheath in pressure contact therewith, while several sets of tubes, separated by corresponding sheaths, may be utilized. The diameter of the tubes may be varied for the sets to compensate for the greater length of tubes at an outer position, so that an approximately equal time of travel from one end of the tubes to the opposite ends may be obtained. The spacing between the successive turns of the coils is preferably a distance corresponding to one half the diameter of the tubes.

Abstract:
Source: CO5970086U 1.– Adaptador para sistemas de succion caracterizado porque esta conformado por tres partes. La primera es el Cuerpo (1) constituido por un cilindro donde se distinguen tres sectores; uno superior que presenta en la zona superior, una perforacion de un diametro muy pequeno (2), y a un lado se desprende un cilindro perforado (4) y ligeramente estriado externamente. Estas perforaciones verticales llegan hasta una perforacion horizontal (6) que atraviesa de manera transversal todo el cuerpo. En el interior de esta perforacion hay una ranura longitudinal (7). Un sector inferior (8), donde el cilindro se adelgaza, esta perforado verticalmente desde su extremo hasta la perforacion transversal, tiene tres estrias y termina en forma de chaflan, Entre la seccion superior e inferior del cuerpo hay un sector de diametro intermedio (9) de forma ligeramente tronconica. La segunda parte es la Llave de derivacion (10) constituida por un cilindro que se desplaza a traves de la perforacion transversal del cuerpo. La llave presenta en un extremo un disco de mayor diametro (11 a) que sirve de tope, un riel (12) que ajusta en la ranura longitudinal de la perforacion transversal del cuerpo y sirve de guia de desplazamiento de la llave de derivacion; presenta una perforacion transversal en el medio (13). Tambien en la parte superior cerca de los discos tope hay dos depresiones (14) una con mayor diametro que la otra. En la parte inferior de la perforacion de la llave de derivacion se amplia el diametro (15) y esta en contacto permanentemente con la perforacion que atraviesa verticalmente el cuerpo del adaptador en sus sectores medio e inferior, El otro extremo de la llave de derivacion se adelgaza formando un pin (16) que tiene como funcion ajustarse en el centro de la tercera parte del dispositivo que es un Disco (11 b) de igual diametro al del extremo de la llave de derivacion. 2.– Adaptador de acuerdo con la reivindicacion 1 caracterizado porque tiene dos perforaciones de diferente diametro, para usar eyectores convencionales y mini eyectores permitiendo la funcion de eyeccion con una sola manguera de succion. 1. Adapter for suction systems characterized because it consists of three parts. The first is the body (1) constituted by a cylinder where three sectors are distinguished; an upper posing on the top, a hole of a small diameter (2), and on one side a perforated cylinder (4) is clear and slightly striated externally. These vertical holes reach horizontal drilling (6) transversely through the body. Inside this perforation there is a longitudinal groove (7). A lower sector (8), where the cylinder is thin, this drilled vertically from the point to the transverse bore, and has three splines shaped chamfer ends, between the upper and lower body section is a diameter intermediate sector (9) of slightly frustoconical shape. The second part is the key derivation (10) consists of a cylinder that moves through the transverse drilling of the body. The key has at one end a larger diameter disk (11) serving as a stop, a rail (12) which fits into the longitudinal groove of the transverse bore of the body and serves as a slider of the key derivation; It has a transverse perforation in the middle (13). Also at the top near the top disc there are two depressions (14) having a greater diameter than the other. At the bottom of the perforation of the key derivation the diameter (15) is wide and is in permanent contact with the drill vertically through the adapter body in its middle and lower sectors, the other end of the bypass key Slimming forming a pin (16) whose function is set in the middle of the third part of the device is a disc (11 b) of equal diameter to the end of the key derivation. 2. Adapter according to claim 1 characterized in that has two holes of different diameter, to use conventional ejectors and mini ejectors ejection function allowing a single suction hose.

Abstract:
Source: GB1486440A 1486440 Fluid regulation RE SELF 5 Dec 1974 [5 Dec 1973] 52562/74 Heading G3H [Also in Division F2] A high–pressure throttling device include a multiplicity of passageways of spiral configuration arranged in parallel flow relationship. In the embodiment shown the device is incorporated in an adjustable valve assembly and comprises a stack of annular discs 38 each provided with a respective row of spiral passageways 40, 41 in each face inter–connected by axial passages 42, 43. Thus fluid entering each passageway via passage 40a, passes around spiral 40b, through passages 42, 41a, around spiral 41b and leaves via passages 43, 44. The fluid may flow in the reverse direction if desired. The discs may be stacked with respective spirals in each row axially aligned to provide communication between passageways in adjacent discs. Alternatively, the spirals may be arranged to overlie lands on the adjacent discs so that the passageways are separate. Each disc may have only one row or more than two rows of spirals. The spirals may be formed in only one face of a disc. The discs may be of stainless steel, bronze, brass or plastics material.

Abstract:
Source: US6283974B A micro surgical phacoemulsification tip wherein a repetitive pattern is etched into the inner lumen surface of a surgical tip in a controlled pattern such that a resonance condition is created which is in harmonic phase with the frequency of the phacoemulsification energy source, thereby reducing destructive interference waves and creating constructive waves; virtually eliminating instantaneous tip temperature spikes and removing the risk of potential tissue burning. More specifically, the present invention is drawn to phacoemulsification needles having a lumen surface having micro–grooved channels positioned thereon which center harmonic phased ultrasonic generated acoustic wavefront interiorly from the needle wall. The micro–grooved channeling of the present invention will work with the axial length of any phacoemulsification needle tip harmonic.

Abstract:
Source: US3231688A (Claim 1) 1. A molded plastic attachment for a telephone handset having a short cylindrical receiver portion and a threaded receiver retaining cap applied thereover, the attachment comprising: a short, hollow cylindrical body portion having first and second ends and having an inner diameter equal at least to approximately the outer diameter of said cylindrical receiver portion; a short, tubular protuberance portion extending axially outwardly from said cylindrical body portion and partially occluding said first end thereof, said protuberance defining with said cylindrical portion a continuous auditory channel funneling respectively from a larger to a smaller channel cross section; and end portion for terminating the end of said protuberance oppo– site from said cylindrical portion and being smoothly formed with said protuberance to fit comfortably against the outer ear of a user, said end portion being partially open to define an acoustical coupling between said receiver portion and the inner ear of said user; and a non– protruding closure portion affixed over said first end of said cylindrical portion for joining with structural continuity the walls of said cylindrical portion to those of said tubular protuberance, the external surfaces of said protuberance portion and said non–protruding closure portion thereby defining an acoustically isolated clearance region about the lobe of the ear of the user.

Abstract:
Source: US2008183206A A vascular filter system and method are disclosed. In one embodiment, the filter system comprises a dispensing needle releasably attached to a filter dispenser which stores a length of filter wire. The filter wire dispenser has a guide tube which guides the filter wire into the needle and then into a vein during surgical implantation. The filter wire is configured to coil into a predetermined shape as it is deployed from the needle. The shape of the filter wire captures blood clots in the blood stream. Once the filter wire is deployed, the needle may be removed and a portion of the filter wire may be left protruding from the patient's skin surface to allow the filter wire to be secured by a fixation device. A syringe may be used to draw blood to confirm that the needle is properly positioned within a vein before the filter wire is deployed.

Abstract:
Source: US5873865A A spiral catheter apparatus for access to, and laser or other treatment within, cavities and organs in the human body, the apparatus comprising a flexible, main catheter shaft defining a central axis of the apparatus, the catheter shaft having a proximal end, a distal end and a first hollow lumen region extending therethrough, the catheter shaft further having a spiral portion adjacent the distal end with a selected curvilinear shape, the curvilinear shape defining an inner arcuate sidewall and an outer arcuate sidewall, the catheter shaft flexible enough to assume a temporarily elongated shape such that the apparatus can be extended through at least a portion of the body in the temporarily elongated shape and will assume the selected curvilinear shape when extended into a body cavity or organ, the selected curvilinear shape serving to securely position the apparatus adjacent a selected surface within the body cavity or organ, at least the spiral portion of the catheter shaft having a plurality of guide holes thereon, the plurality of guide holes disposed at least on the outer arcuate sidewall in communication with the first lumen such that a distal end of a laser delivery means or other functional device can be controllably advanced through the plurality of guide holes for laser or other treatment on the selected surface.

Abstract:
Source: US2001031058A A hearing aid assembly having a directional microphone mounted externally to a hearing aid body is disclosed. The hearing aid, which may be, for example, an in–the–canal (ITC) or completely–in–the–canal (CIC) hearing aid, has a mounting arm attached to an external surface of the hearing aid body, and the mounting arm in turn has a directional microphone mounted therewith. The mounting arm provides mechanical and electrical connection between the directional microphone and the hearing aid. The mounting arm is also configured such that, upon insertion of the ITC or CIC hearing aid into the ear canal of a wearer, the microphone is located in the region above the tragion portion of the ear.

Abstract:
Source: US2014222039A The present invention relates to a surgical anchor device (1) suitable for being anchored on the mucous membrane of the inner wall of the intestine (10), the device comprising a temporary anchor element (2) presenting anchoring that can be modified in controlled manner and comprising a first substantially cylindrical multiply−perforated wall presenting properties of radial elasticity whereby said first wall presents an outer diameter that can be varied in controlled manner, the device being characterized in that at least a portion of the inner surface of said first wall (2a) is lined with an independent leakproof inner sheath having only its longitudinal ends (3a, 3b) fastened to said anchor element (2) in such a manner as to define a suction chamber (5) between said inner sheath (3) and said first wall, said temporary anchor element (2) being coupled to a flexible or semi−rigid tube referred to as an "injection−suction" tube (6), extending outside said anchor element (2), an

open end (6a) of said injection–suction tube opening out into said suction chamber (5) enabling air to be injected into or sucked out from said suction chamber.

Abstract:
Endoscopic surgery system, for catching and closing anheart auricle in such a way to prevent the blood flow into the auricle cavity, comprising: –a ring–shaped tightening element (3), which tightens a noose (2) around the auricle to be occluded;5 –a main hollow body (4); –a push slider (7), housedin the main body (4) and sliding therein, whose push member (7) in turn has a proximal portion (10) perforated longitudinally in such a way to allow the passage of the noose (2)ends, such proximal portion (10) being capable to cooperate with the tightening element (3) in such a manner to drivingit intothe 10 occlusionmovement. Abstract:
The invention relates to a medical device for the recanalisation of body cavities (20). Said device comprises a recanalisation element (10) that can be inserted into the body cavity (20), can be converted from a compressed state into an expanded state and has, in said expanded state, a tubular hollow body (11) such that the body cavity (20) can be recanalised, the outer contour of said recanalisation element (10) forming at least one helical winding (13). In addition, the invention relates to a set comprising such a device and a supply system (40).

Abstract:
A prosthesis to replace a venous or cardiac valve comprising a valving element in the form of a plurality of spirally–arranged, partially overlapping and facially abutting layers, said valving element being made in a single piece from a thin, elastic material, the end of its outer turn being fixed to an annular supporting ring and the end of its final turn terminating in a capping piece which acts as a central closure of said layers; in their collapsed, abutting state, said partially overlapping layers acting to provide a complete obstruction to flow in one direction but, when pressure is applied to them from the counter direction, lifting and elastically separating in a mode similar to that of the coils of a very light spring; opening of said valve involving only a small torsional distortion distributed more or less equally throughout the whole length of said valving element.

Abstract:
Source: GB385898A [Class 39 (i).] A cathode glowdischarge lamp operating on direct or alternating current, and especially suitable for use with direct current of 100–110 volts, comprises closely spaced electrodes coaxially arranged within the envelope and each coated with an alkali or alkaline earth metal, at least one electrode being of helical form while the other is so constructed as to be capable of being heated to a high temperature by high frequency induction. In one construction, Figs. 3 and 4, one electrode is constituted by a hollow cylinder 5, preferably of nickel or nickel–plated iron, closed at its upper end, and the other by a helix 9, preferably of nickel–plated iron, mounted concentrically around the cylinder. Leads 2, 3, preferably of copper–coated nickel wire, are sealed through the stem press 4, the lead 2 being connected to a transverse supporting member 6, preferably of nickel, within the cylinder 5, and the lead 3 extending through an opening in the top of the cylinder for connection to the helix 9. A tubular vitreous sheath 7 serves to insulate the lead 3 from the cylinder 5 and its upper end provides a further point of support for the cylinder. A downward extension of the support 6 carries a tubular vessel 10, preferably of iron, open at its lower end and enclosing a small quantity of magnesium 11 to serve as a getter. In a modification, Figs. 6 and 7, the leads 21, 31 sealed through the stem press 4 pass through longitudinal passages in a cylinder 12 of lavite, porcelain or other suitable insulating material mounted within the' cylindrical electrode 5<1>. The lead 2<1> is spot welded to a tab 14 punched up from the top of the cylinder 5<1> while the lead 31 passes freely through an opening in the top of the cylinder 5<1> for connection to the helix 9. The getter vessel 10 is carried by a wire 13 which passes through a third longitudinal passage in the cylinder 12, its'upper end being bent over and held between the tops of the cylinders 12 and 5<1>. In each case the electrode structure is first assembled with the exception of the electrode 9. The electrode 5 or 51 is then coated with an alkali or alkaline earth metal compound decomposable to the oxide, e.g. barium or strontium carbonate or potassium hydroxide. The electrode 9 is then mounted, the stem 4 is sealed into the envelope, and the lamp is heated to 450 C. for 10 mins. while maintaining a high vacuum for the removal of occluded gases. A high frequency coil is then held for 15 secs. with its axis normal to that of the electrode structure to raise the temperature of the electrode 9 to about 600 C. to remove from its surface any oxide. The coil is then placed with its axis in line with that of the electrode structure to raise the temperature of the electrode 5 or 5<1> to about 1000 C. for a time sufficient to effect the decomposition of the carbonate or hydroxide to the oxide. The coil is then lowered to concentrate. its heating effect on the magnesium 11 to vaporize it. The envelope is then filled with mercury vapour, neon, helium or other suitable gas or vapour, or mixtures thereof, e.g. neon containing 0.2 to 0.8 per cent. of argon at 35 mm. pressure. After sealing off, the lamp is connected to a source of pulsating or

alternating potential of steep wave front to produce a bombardment of the electrode 5 or 5<1> serving to reduce some of the oxide to the free metal and to sputter some of the metal on to the electrode 9. To obtain a more uniform coating on this electrode it is preferred to use an unsymmetrical alternating current such that the half cycle of greater potential occurs when the electrode is negative. Fig. 8 shown a modified construction in which two helical electrodes 24, 25 are employed, the turns of each helix being shortcircuited. The helix 24 is connected at each end to the lead 22 and the helix 25 at each end to the lead 23 and the turns of one helix are evenly spaced between those of the other. Both electrodes are coated with the alkali or alkaline earth compound which is subsequently decomposed to the oxide by the heat generated in the closed circuits of the helices by a high frequency field and thereafter reduced to the free metal by the action of an alternating potential between the electrodes. Specifications 162,268, [Class 39 (i), Electric lamps, Arc c.], and 362,346 are referred to.

Abstract:
The invention relates to a system for distilling seawater by using a spiral turbine which drives an air injector that uses a conical screw with a decreasing pitch. The compression of the air, by means of heating with gas, vaporises the seawater, the expansion of the gas subsequently causing the distilled vapour to precipitate as pure water. In addition, the system recovers the pneumatic and hydraulic energy associated with the purifying process, by using identical turbines, respectively inserted into the hydraulic and injection–based pneumatic circuits obtained from the precipitation of the water vapour generated, the energy being used in any type of work.

Abstract:
Source: US2007083195A Devices, systems and methods are disclosed for the ablation of tissue. Embodiments include an ablation catheter that has an array of ablation elements attached to a deployable carrier assembly. The carrier assembly can be constrained within the lumen of a catheter, and deployed to take on an expanded condition. The carrier assembly includes multiple electrodes that are configured to ablate tissue at low power. Additional embodiments include a system that includes an interface unit for delivering one or more forms of energy to the ablation catheter.

Abstract:
Source: EP2898842A1 A tool for delivering and applying a clamping implant (9; 109) via a puncture in skin tissue (3) and underlying tissue (2) of a patient, comprising a hollow needle (4; 104) bounding a lumen (5; 105) and forming a helix, a plunger (6; 106) of which a distal portion extends in longitudinal direction inside the lumen (5; 105), and a plunger operating member (7; 107) engaging a proximal portion of the plunger (6; 106) projecting from the needle (4; 104), for screwing the plunger (6; 106) further into or out of the needle (4; 104) by screwing rotation of the needle (4; 104) relative to the plunger (6; 106). A system including such a tool and a method for delivering and applying a clamping implant (9; 109) using such an instrument are also described.

Abstract:
Source: US3307515A (Claim 1) 1. In an apparatus for vapor−phase deposition of a resistive film on a plurality of electrical resistor substrates, an inclined hollow cylindrical kiln having a resistance heating coil traversing the inside diameter thereof, a rotatable reaction chamber concentrically disposed adjacent the inside diameter of said resistance heating coil, said reaction chamber comprising a metal tube having a helix of wire fixedly disposed along its inside diameter, spray means substantially penetrating one end of said reaction chamber for introducing and atomizing a deposition solution within said chamber said spray means comprising a nozzle having a first tubular passage for introducing said deposition solution and a second tubular passage concentric with and surrounding at least the penetrating portion of said first passage, means for passing atomizing air through said second passage to thereby control heating of said deposition solution prior to discharge and atomization thereof, substrate entrance means adapted to introduce said substrates into said reaction chamber, said reaction chamber being adapted to advance and tumble said substrates at a predetermined rate during deposition, discharge means allowing exit of the coated substrates from said reaction chamber, exhaust control means adapted to remove from said reaction chamber the gaseous products resulting from the vapor−phase reaction, the reaction chamber ends being substantially blocked from external atmospheric contamination, and the coefficient of thermal expansion of said reaction chamber being sufficiently different from that of the deposition material so as to cause dislodgement of accumulated coating deposits when said apparatus is allowed to cool.

Abstract:
Source: US2005125034A An active suture that can be used for both wound closure and the delivery of therapeutic fluids to the tissue surrounding a wound is disclosed. The active suture may include a connector designed to join a fluid source, such as a syringe or conventional IV delivery system, to an internal passageway that is embedded within a braided suture. The internal passageway may be comprised of a fine polymeric tube and is capable of conducting and emitting a fluid into at least a portion of the braided suture and surrounding tissue. The invention enables delivery of an efficacious volume of drug bearing solution on the order of milliliters per day, provides a high level of fluid delivery rate control enabling the physician to start or stop drug administration at his/her discretion, and offers a means of providing more than one type of medication that may be selected post−surgically in accord with unexpected patient symptoms that may arise.

Abstract:
A filtration assembly including: i) a hyperfiltration assembly including: a high pressure vessel including a feed port, concentrate port and permeate port, and a plurality of serially arranged spiral wound hyperfiltration membrane modules; ii) a bioreactor assembly including: a plurality of spiral wound bioreactors each comprising a flat sheet having two opposing bio–growth surfaces and a feed spacer spirally wound about an axis (Y); and iii) a fluid flow pathway adapted for fluid connection with a fluid feed source and extending in a parallel flow pattern through the bioreactors, and subsequently into the feed port of the high pressure vessel, successively through the spiral wound hyperfiltration membrane modules in a serial flow pattern and out of the concentrate port and permeate port.

Abstract:
Source: US2009095235A An instantaneous heat exchanger for heating sanitary water in a combined boiler has a casing defining a chamber for a first fluid, within which there extends a conduit or tubing for a second fluid. At least one of the chamber and the conduit has a substantial capacity of containment of the respective fluid, preferably between three and six litres, and the heat exchanger is pre–arranged for hydraulic connection to a standardized connection assembly for an ordinary plate–type heat exchanger for a combined boiler.

Abstract:
Source: GB758416A 758,416. Concentrating solutions by freezing. COMMONWEALTH ENGINEERING CO., OF OHIO. Aug. 16, 1954 [Sept. 14, 1953], No. 23782/54. Class 29. Aqueous solutions. are concentrated by freezing in successive stages refrigerated at progressively lower temperatures, each stage being performed in a tank 10... 14 refrigerated by hollow cylinders 25 through which refrigerant e.g. brine is passed, the mixture of ice crystals and concentrated solution being withdrawn after each stage through one of the pipes 31 to a common header 30 where the ice is separated from the solution which is forwarded to the next stage. Each tank contains an agitator 22 driven by a motor 23 and three cylinders 25. Solution is supplied to the first tank 10 through a connection 60 and flows from the header 30 to a sump 33 whence it can be withdrawn for use through connection 36 or supplied by a pump 39 to one or other of the tanks through electrically–actuated valves 51... 54 and connections 56... 59. Brine at a temperature below that of the coldest tank 14 is supplied from a tank 80 by a pump 81 and flows in parallel to each tank, where it flows in series through the three cylinders 25. The brine flow to each tank is controlled by a valve 87 (in Fig. 1, denoted by 101, 100, 102, 104, 103, respectively) actuated in response to the temperature of the brine leaving the last cylinder of the three, this temperature being detected by a thermal element 90 connected to an adjustable controller 94 which is set to the temperature which it is desired to maintain in the associated tank. A by–pass 96 around each valve 87 allows a small flow of brine through the system to ensure actuation of the control apparatus. Brine from the tanks is returned to tank 80 through pipes 75 and common pipe 76. In each cylinder the brine flows down a central tube 63, across the bottom and upwardly through an annular passage 62 containing a spiral baffle 68. To remove ice from the outer surface of the cylinder, hot air may be passed through it or an electric heater may be embodied in the baffle 68 and is intermittently supplied with current.

Abstract:
Source: GB783468A 783,468. Centrifugal pumps. BORGWARNER CORPORATION. June 6, 1955 [Nov. 3, 1954], No. 16146/55. Class 110 (1). A pump comprises an impeller having one or more helicoidal vanes extending around a conical hub, the total length of the channel or channels defined by the vane or vanes being greater than any circumference of the impeller, and the cross–sectional area of the channel or channels decreasing continuously from the inlet towards the outlet. Fig. 1 shows a booster pump mounted by means of a flange 14 on the bottom wall of an aircraft fuel tank and driven by an electric motor 13. The impeller is of conical form, with spiral vanes 21, the relative inclination of the impeller hub 25 and the conical housing wall 23 being such that the cross–sectional area of the flow passages 22 between successive vanes 21 decreases from inlet to outlet. The resultant pressure increase condenses vapour contained in the fuel. Fuel enters the pump through a screen 15 and is discharged by way of a volute 18 to an outlet 20. Inlet guide vanes 16 are provided. Instead of being parallel to the plane of rotation of the impeller, the leading edges of the vanes 21 may be at an angle to it. The conical wall 23 may be replaced by a cylindrical wall. The impeller may be hollow so that vapour contained in the fuel can rise through the hollow impeller and escape back to the tank. In a modification, the pump is inverted and mounted below the bottom wall of the tank, with a screened inlet protruding into the tank.

Abstract:
Source: GB1017183A 1,017,183. Pug−mills. PIRELLI S.p.A. June 25, 1962 [July 19, 1961; Oct. 17, 1961], No. 24257/62. Heading B1C. [Also in Division B5] A rubber mixer has a frusto−conical screw 5, Fig. 1 (not shown), with a spiral−helical flight 7, arranged in a frusto−conical housing 4 in such a manner as to form at least one chamber 12 in which material can circulate; as depicted, the cone angle of the screw is less than that of the housing, to which the screw is tangential along a line, so that the volume of the channel in the screw decreases towards the discharge end and there is an angle between the axes of the screw and housing; the single chamber 12 thus formed is crescentshaped in cross−section. Alternative arrangements could comprise a screw of circular cross−section in a housing of elliptical or triangular cross−section, or a screw of elliptical or triangular cross−section in a housing of circular cross−section, providing more than one chamber. In the embodiment of Fig. I the screw has a cylindrical extension 10 carried in an outrigger bearing 9, and the size of the annular discharge gap 3 (and hence the intensity of mixing) may be varied by adjusting the sleeve 20. The product is extruded as a tube which is cut into a helical strip by a fixed knife 28 (see Fig. 3, not shown). Both the screw and the housing have chambers for a heat exchange fluid; the screw may have a single− or multi−start helix and the flight may be thickened to provide increased shear effect (see Figs. 5 and 6, not shown). In other embodiments the screw may have a cyindrical screw extension fitting closely in a cylindrical housing and forming an extrusion section, and the material may be extruded as a rod or other shaped section through a detachable die (see Figs. 7 and 8, not shown).

Abstract:
Source: US2008275301A A medical instrument used as a sigmoidoscope (1) for internal examination of the rectum and sigmoid colon of a patient. The instrument includes an outer tubular member in the form of a speculum (2) having a forward insertion end (3) and a rearward observation end (4). An inner tapered guide tube (10) is disposed at least partially within the speculum (2). A retractable obturation tube (15) is disposed between the speculum (2) and the inner guide tube (10) for relative movement between a retracted position substantially within the speculum (2) and an extended position in which the obturation tube (15) protrudes longitudinally beyond the forward end (3) of the speculum (2).

Abstract:
Source: US4700716A A microwave collinear antenna array applicator for in situ or in vivo treatment of tumors and/or other materials by hyperthermia is disclosed. The array consists of a plurality of harmonically related resonant coaxial antenna elements connected electrically in series to provide uniform heating along the entire length of the array. At the distal end of the array, a resistor may be provided at the inner conductor for steering the heating pattern. At the proximal end of the array, an impedance matching dielectric structure is provided to enable maximum power transfer to the array and to minimize stray leakage currents along the outside of the coaxial transmission line. The array may be made longer or shorter without changing frequency and therefore depth of penetration by simply adding or subtracting half−wave resonant elements or sections of coaxial transmission line. A lossy sleeve member may be provided around the applicator to provide a localized source of heat.

Abstract:
The invention provides optical guidewires (10) for obtaining optical radiation from within a body lumen. The optical guidewire includes an optical fiber (20) attached to a ferrule (12), and a hollow shaft (14) with at least one window (16) or aperture (18). The proximal end of the shaft is configured to engage the ferrule with either a releasable engagement (allowing the ferrule to rotate after separating from the shaft), or a rotating engagement (allowing the ferrule to rotate without separating from the shaft). The windows (16) or apertures (18) may be circular, square, rectangular, hexagonal, or other shapes, and may be placed in an equatorial, spiral, or other pattern around the shaft or at the distal tip of the shaft. A window may be translucent or transparent, and preferably has an index of refraction of about 1.34, similar to blood plasma. The optical fiber rotates within the shaft adjacent the window or aperture to provide an optical scan.

Abstract:
Source: US3139466A 973,471. Moulding articles of foamed resins. D. BLOOM. March 22, 1961 [March 28, 1960], No. 10858/60. Heading B5A. In a method of moulding articles of expanded plastics material, e.g. polystyrene, the mould is preheated and charged with material while substantially closed, the material then being expanded in the mould, the charging of the mould being effected by a stream of compressed air, which entrains the expandable material and carries it into the mould. The moulds are formed in two parts 10, 12, Figs. 1, 3, 4, and are mounted in alignment on supports 14, 16 respectively, which contain adjustable spaced bars 28 so that a variety of different moulds may be accommodated. Each mould part 10, 12 is mounted on a flange 18, which is secured to the bars 28 either by bolts 19, Fig. 1, with packing pieces 23 if required, or by the use of clamping pieces 20 and bolts 22, Fig. 3, in which case dowels 21 are provided to position the mould parts accurately in holes in the bars 28. The support 16 is fixed and the support 14 is reciprocated on bars 36 to open and close the moulds by actuation of an hydraulic cylinder 40 and piston 42, connected to the support 14 by a connecting rod 48 with an adjustable threaded portion 50. Each mould part 12 is fitted with a charging device C. Heating and cooling mould parts (Figs. 3, 4).– The mould parts 10, 12 are heated by steam supplied to pipes 74, 84 respectively and leaving through pipes 76, 86. Holes 92 in the mould part 10 allow the steam to heat the closed mould space. Alternatively, the mould parts may be cooled by circulation of cooling water. In addition a filling orifice 66 is provided in the mould part 12. Mould charging device (Fig. 6).–This comprises a tube 94 connected with the orifice 66 by the use of a flange 100. A junction tube 95, part of which is preferably transparent, and a flexible duct 96 lead to a bin 98, Fig. 1, containing granular partially pre–expanded material. A hollow collar 104 is provided on the tube 94 and communicates with the inside of the tube 94 by means of drillings 108 which are made at an angle to the axis of the tube 94 and at an angle to the diameter thereof to enable compressed air supplied to pipe 106 to create a

vortex of air in the tube 94, so lowering the pressure in the tube 95, so that material is drawn up through the duct 96. V−shaped vents 110 are provided in the tube 94 to allow escape of some, but not all, of the air flowing therethrough, and a slip ring (not shown) may be fitted over the vents 110, the slip ring being provided with slots to register with the vents 110, so that the escape of air may be regulated. A cooling sleeve 124 is also provided and water circulated therethrough to ensure that material in the tube 94 does not expand before entry into the mould. After filling of the mould a piston 144 is moved through the tube 94 and into the orifice 66, Fig. 4, by operation of an hydraulic cylinder 134, screw−threadedly mounted on the tube 94. The tube 94 may project beyond the flange 100. Operation.−The moulds are closed by operation of the cylinder 40 so that a stop 56, Fig. 1, passes under a catch 52. The fluid supply to the cylinder 40 is reversed and the moulds are held slightly open by the engagement of the stop 56 and catch 52. The mould parts and the mould space are heated by steam and the mould space is allowed to dry out thereafter, compressed air then being supplied to the collar 104 to blow material into the moulds. The gap between seatings 60, 62, Figs. 3, 4, on the mould parts 10, 12 respectively is not large enough to allow escape of the granules of material which are trapped in the mould and start to expand. When the mould is full, air can no longer pass therethrough due to the expanded material, so air which cannot escape through the vents 110 passes back down the tube 95. The piston 144 is then advanced and steam again supplied to the mould parts to complete the expansion, after which cooling water is circulated in the mould parts. The mould is then opened to remove the finished article.

Abstract:
The invention concerns a self–expanding vascular prosthesis in particular for intracranial aneurysm shaped like a cylindrical sleeve (2) and consisting of a helically wound thin elastic metal ribbon whereof the external diameter when manufactured is substantially greater than the treated vessel (6) internal diameter and capable of being compressed by increasing the number of coils to be inserted in a catheter to be for setting it in place, the expansion resulting from the ribbon being unwound when the sleeve is ejected from the catheter by a thruster provided therefor and sliding in the catheter. Said prosthesis is designed to be surgically set in an artery to prevent locally risks of internal haemorrhage caused by a burst aneurysm, and particularly designed to be used in cervical vessels.

Abstract:
Source: NL7608927A The screw–type pile has a blade following a spiral path, by means of which it is driven into the ground. There are a number of spiral blades (2) fixed to the pile (1) at intervals in the axial direction, the intervals concerned being the pitch of the spiral. Each blade can extend through one complete turn, with its ends overlapping. The blades can alternatively extend each through several turns, and their ends can be offset in relation to each other in the peripheral direction. The distance between the multi–turn first blade and the second one can be designed to suit the structure of the subsoil into which the pile is driven.

Abstract:
Appliance in continuation of laid−open specification WO 86/01728 and Japanese Application J 211352/86 for metabolic control, in particular in diabetics, the substance measurements, in particular of the blood glucose, being carried out alone or else in combination with an injector influenced by the substance measurement results, using a control device and a switching gear for the automatic functioning (on account of the problems, which have obviously not yet been adequately solved, in respect of injury−free substrate determination by means of laser light) preferably using a type of sensor canula (or a puncture stylus) for low−injury aspiration of blood, using a suction channel (preferably as a pressure compensation channel) using a suction cup in connection with a reliable vacuum source, so that it is possible, after a controlled duration of action of the blood inside a reaction chamber on an indicator layer, in this case preferably an optical version, to remove the blood therefrom and to convey light measurement changes from the indicator layer to a reflex photometer, which can be situated in a separate housing; in the case of an intended improvement in metabolism by injection, preferably through the same cannula support used for obtaining blood, via at least one tube−integrated metering device, preferably near the cannula, in the presence of at least two equivalent liquid containers with valve coupling per medicament type for a low−residue administration of different quantities of liquid, with inclusion of a reflex−photometric control in order to prevent puncturing of pathologically altered skin.

Abstract:
Source: US4818551A A shirred stick composed of unreinforced casing impregnated with liquid smoke. The stick has no twist which eliminates rope and gives the stick a smooth, blemish free outer peripheral surface. The method of making the stick requires placement of the shirred stick on a dowel immediately after shirring, holding it on the dowel for a period of time sufficient for moisture to migrate uniformly throughout the stick and then removing the dowel.

Abstract:
The present invention relates to a device for inseminating animals, mainly sows. This device includes a catheter (1) for forwarding the sperm which is introduced in the vagina. The catheter comprises a bead (2.1, 2.2, 2.3, 2.4) in the area of the end to be introduced (1.1), as well as an essentially sleeve–shaped hollow body (6; 16) to be introduced at the start of the vagina and through which the bead and the catheter can be pushed into the vagina. In order to prevent sperm reflux in a simple manner, the bead (2.1, 2.2, 2.3, 2.4) is made of cellular foam or the like. Before being introduced into the organic cavity, the bead can be compressed on a cross section which is smaller than the lumen of the organic cavity. The bead further expands, after an expansion time as it reaches the end position corresponding to the uterus of the animal, until the animal's organic cavity is occluded by a soft retractable plug (20).

Abstract:
Source: FR2349736A (Claim 1) 1) Dispositif universel pour neutraliser la toxicite des gaz d'echappement des moteurs a explosion par leur synchronisation avec une postcombustion silencieuse des hydrocarbures imbrflles et de l'oxyde de carbone dans un melange combustible riche en oxygene produisant du gaz carbonique et de la vapeur d'eau, caracterise par le fait que les moyens generalement utilises comprennent deux ensembles relies mais differencies par leur mode de fixation au vehicule j d'une part, l'accouplement d'une pompe a injection et d'un ventilateur centrifuge, mis en action par le moteur a explosion, est li brement solidaire du bloomoteur 3 les raccordements des deux ensembles sont de types souples entre la pompe a injection et son injecteur et entre le ventilateur et le diffuseur, ou de type rigide entre le collecteur des pi pes dtechappement du moteur a explosion et le diffuseur; d'autre part, 1' autre ensemble, suite d'elements rigidement solidaires entre eux et librement solidaires de la carrosserie par silenblocs, compte un diffuseur, un me canisse anti–retour de flamme, une chambre de postcombustions un echangeur thermique avec canal de VEhfbRI, et un silencieux. A device for reducing the pollution due to the exhaust gases from an internal combustion engine has an inlet supplied with air from an engine–driven fan. The air mixes with exhaust gases which enter through another inlet and the mixture flows through the flame trap into the post–combustion chamber. The post–combustion chamber is provided with a fuel jet connected to an engine driven pump. A sparking plug initiates combustion so that all unburnt fuel in the exhaust gases is completely burnt. Once combustion has been initiated the sparking plug and fuel jet are disconnected. The pollution free gases then flow through the heat exchanger and through the venturi before flowing into the silencer.

Abstract:
Source: US2007207186A The present invention is a more durable expanded material that enables thinner wall thicknesses and a more flexible reinforcement suitable for stenting. The present invention is especially useful in the construction of grafts, stents, and stent−grafts which are used, for example, in repairing or replacing blood vessels that are narrowed or occluded by disease, aneurismal blood vessels, or other medical treatments. The inventive material and configurations allow expansion or contraction in size or adjustment in size in an incremental manner so that the optimum size, shape, and fit with other objects can be obtained. The present invention is also optionally capable of more accurately delivering one or more active ingredients such as drugs over longer periods of time. The present invention optionally includes surface modifications and additives that increase the surface adhesion of active ingredients, coatings, or combinations thereof. Finally, the present invention optionally includes growing cells on the inventive material so that the expanded material, reinforcement, or combinations thereof are useful, for example, in producing lab−grown blood vessels or organs.

Abstract:
Source: GB700494A 700,494. Cables. PIRELLI SOC. PER AZIONI. March 31, 1952 [April 18, 1951], No. 8099/52. Class 36 The gas distributing tubes of single or multicore gas pressure cables are provided with perforations which, of themselves or in co–operation with an auxiliary member, act as valves, allowing the free flow of gas outwardly from the tube, but preventing the flow of insulating compound or gas in the reverse direction. In a multicore cable having impregnated paper filling 12 in the spaces between the cores, one or more of these spaces also includes a metal helix 4 enclosing an elastic tube 5 which may have an internal metal helix 6. The tube 5 is provided with small apertures 14 made by puncturing with a needle or thin blade and spaced so that they are not obstructed by the turns of the helix 4. Internal pressure opens the apertures, but external pressure holds them tightly closed. The tube 5 may be replaced by a metal tube having perforations of finite diameter. An elastic tape is tightly wound on this tube so as to close the perforations but allow the escape of gas under pressure from within the tube. The cable may also include a signalling cable 7 and an unperforated tube 8 to convey gas through a length of the cable without permitting its distribution. In a single core cable the helix 4 forms an axial passage within the hollow stranded conductor and embraces either the elastic or metallic tube above described.

Abstract:
Source: DE19513568C1 Prepn. grinder inlay system consists of a grinder and a prefinished ceramic moulding, which are co–ordinated w.r.t. each other so that the moulding fits exactly into a cavity. The grinder (1) consists of a wheel with a shaft (2) which has conical side surfaces (3) and a rounded off running surface (4). The grinder rotates or oscillates during cavity preparation. The max. height of the section is determined by the spacing between the running surface (4) and the shaft (2), and this decides the max. penetration of the grinder.

Abstract:
Source: US2001018861A A sensor mountable within a hydraulic cylinder provides a precision signal indicative of the position of the piston. The sensor includes a flexible connector attached between the cylinder piston and a converting element for sensing the piston displacement. The converting element comprises a pick–up spool, under tension, coupled to the other end of the connector and rotatable about an axis. A lead screw engages threads on the spool, and translates linearly when the spool rotates. A non–contacting electromechanical transducer senses the position of the lead screw, and provides an output signal proportional to the motion or position of the movable element. The transducer may be an LVDT or other transducer. A high–pressure seal assembly provides an electrical path between the sensor and an external connector. A piston stop prevents the piston from damaging the sensor. The sensor is held within the cylinder by port inserts threaded into standard cylinder hydraulic fluid ports and advanced inwardly to grip the sensor.

Abstract:
Source: US2010057067A A cryogenic medical device for delivery of subcooled liquid cryogen to various configurations of cryoprobes is designed for the treatment of damaged, diseased, cancerous or other unwanted tissues. The device is a closed or semi−closed system in which the liquid cryogen is contained in both the supply and return stages. The device is capable of generating cryogen to a supercritical state and may be utilized in any rapid cooling systems. As designed, the device comprises a number of parts including a vacuum insulated outer dewar, submersible cryogen pump, baffled linear heat exchanger, multiple pressurization cartridges, a return chamber, and a series of valves to control the flow of the liquid cryogen. The cryogenic medical device promotes the subcooling to any external cryogenic instrument.

Abstract:
Source: FR1558868A (Claim 1) 1. La piece intercalaire est fabriquee par extrusion sous la forme d'un materiau en forme de barre, en substance synthetique et elle est coupee a longueur en fonction de l'epaisseur du mur en beton a eriger. La figure 1 montre une piece intercalaire qui est constituee par un corps cylindrique 3 pourvu d'un alesage longitudinal 2 et presentant dans le sens longitudinal plusieurs nervures de renforcement 4 s'etendant en helice. Afin que les nervures de renforcement 4 ne se detachent pas du corps cylindrique 3, l'epaisseur des nervures augmente. en direction de l'alesage axial

Machine translation: (Claim 1) 1. The insert piece is manufactured by extrusion in the form of a bar−shaped material, synthetic and essentially it is cut to length depending on the thickness of the concrete wall was erect. Figure 1 shows a spacer which consists of a cylindrical body 3 provided with a longitudinal bore 2 and having in the longitudinal direction several reinforcing ribs 4 extending helically. So that the reinforcing ribs 4 do not come off of the cylindrical body 3, the thickness of the ribs increases. towards the axial bore

Abstract:
Source: US4427637A An apparatus is disclosed for producing an alkali metal salt of a mineral acid, characterized by the provision of a specific agitating means, said agitating means having a pair of shafts adapted to contra–rotate and a plurality of columnar agitating elements securely attached to each of said pair of shafts and being so constructed that it forcibly causes the migration of the reaction mixture at least in the region where the liquid phase of the reaction mixture is substantially continuous and forcibly causes the kneading of the reaction mixture at least in the region where the solid phase of the reaction mixture is substantially continuous. A process is also disclosed for producing an alkali metal salt of a mineral acid, characterized in that the reaction between an alkali metal chloride and a mineral acid is effected in the apparatus as described above while allowing the state of

the reaction mixture to be transferred from a slurry or capillary state to a pendular or dry state via a funicular II state and a funicular I state with the progress of the reaction; that the reaction mixture is impelled to migrate at least in a region ranging from the zone in which the reaction mixture assumes a capillary state to the zone in which the reaction mixture assumes a funicular I state; and that the reaction mixture is forcibly kneaded at least in a region ranging from the zone in which the reaction mixture assumes a pendular II state to the zone in which the reaction mixture assumes a pendular state. Thereby, a desired product can be continuously, stably obtained with high efficiency.

Abstract:
Source: EP0406787A2 A case (1) for single– or multi–stage pumps having at least one centrifugal radial impeller, and a method for the manufacture of such case with metal plate. The case includes, for each stage and for each impeller, a substantially cylindrical lateral wall (2) and a device (15) for diffusing and directing the flow delivered from the impeller of each stage, which case has, in the lateral wall thereof, at least one volute with a uniformly increasing transverse cross section which is outwardly closed and is formed by an initial portion (17), an intermediate portion (18) and a final portion (19) which are mutually blended in a continuous manner. The initial and intermediate portions extend circumferentially to collect and diffuse the radial flow to the delivery port (4) of the impeller, whereas the end of the final portion is axially offset with respect to the initial and intermediate

portions and is directed inwardly of the case to convey the flow toward a central region of the pressure chamber adjacent to the impeller.

Abstract:
A dilatation catheter (1) for reducing or eliminating vascular constrictions or vascular occlusions (2) has at its distal end at least one pressure element (3) and, possibly, also a second pressure element (16) which is spaced apart from the first pressure element (3). The pressure element or pressure elements are used to exert a pressure on the constricted vessel wall in order to force back deposits which are present there and in this way to once again enlarge the inner lumen of the vessel (4). For this purpose the catheter (1) is mounted rotatably and can be connected at the proximal end to a rotational drive mechanism (5). In order to be able to produce inside a vessel (4) a greater circumference or cross−section than is predetermined by the pressure element(s) (3 and/or 16), the catheter (1) has an inner guide channel (6) for a stylet (7) and is flexible near the pressure elements (3 and 16) so that it can be bent or deflected. Near its end (8) projecting in the use position up to or into the pressure elements (3) or the pressure elements (16), the stylet has as a supporting and guiding means a first bend or curve (9) and can in turn be coupled to a rotational drive mechanism (5) and can in this way be driven in rotation, preferably in synchronism with the catheter (1) so that the pressure element or pressure elements are moved not only about their own axis, but at the same time eccentrically in a circular orbit.

Abstract:
Source: GB1001992A 1,001,992. Rollers. FIBREGLASS Ltd. Aug. 4, 1964 [May 10, 1963], No. 18539/63. Heading F2U. Apparatus for the reinforcement of a settable material, such as polyester resin, with a fibrous material, such as chopped strand glass fibre mat, includes a hollow roller preferably made of metal and provided with perforations for the flow of the resin to the surface of the roller, which is of discontinuous form to permit the escape of air removed from the fibrous material. As shown in Fig. 2, the surface of the roller has annular ribs 5, with radial perforations 3 in the intervening channels 4. In an alternative form, Fig. 1 (not shown), the ribs 5 are helical. In Fig. 6 the roller has perforations 12 and longitudinal ribs 11 which may be continuous or interrupted. The ribs may be integral with the roller body as shown, or detachable, in which latter case they may be of metal or rubber. A number of sections may be secured together axially to form a long roller, and the roller may be tapered or barrel–shaped.

Abstract:
Source: US5113855A A powdered medication inhaler is provided which comprises a body having a hollow chamber of substantial height. Powdered medication is transferred from a hopper by a dosing blade having an amperture therein to a transfer station opening into a chamber. In most embodiments of the invention the transfer station is adjacent the upper portion of the chamber, but in one embodiment it is adjacent the lower portion thereof. When the transfer station is adjacent the upper portion of the chamber it includes a pallet or cup on which powdered medication is dropped or blown from the dosing blade. Gas then carries the medication from the cup or pallet into the chamber for inhalation by a patient. In the embodiment in which the transfer station is adjacent the bottom of the chamber compressed gas blows the powder up into the chamber.

Abstract:
Source: US5765510A A retractable sootblower for avoiding and dislodging accumulated soot and ash. The sootblower includes an elongate housing and a blowing tube or blowing tube assembly reciprocable in the housing. The blowing tube is extended and retracted by pressurized gas. Pressurized gas is also applied to the sootblower. An internal gas channeling arrangement couples the pressurized gas to the blowing tube when the blowing tube is extended. The pressurized gas is thus discharged from the blowing tube when the blowing tube is extended. Additional structure is provided for rotating the blowing tube as it moves from the retracted position to the extended position.

Abstract:
Source: US2003078608A A medical device is provided for removing material from a body vessel comprising a tube, a drive shaft extending through the tube, a cutter member rotatable around its access having a tip and relatively sharp cutting edges extending outwardly from the access, and a housing enclosing the cutting edges of the cutter member so that the tip of the cutter member extends outside the housing to cut material in cooperation with the housing.

Abstract:
Source: US3540993A A safety closure cap having a first closure member and a second closure member rotatably retained therein. The second closure member may be screwably attached to a container, so that the cap closes the container by rotation of the first closure member in the closing direction, the two closure members being coupled together for this purpose. For removing the cap from the container the cap is provided with a further coupling arrangement which can be engaged when the two closure members are moved together, rotation of the first closure member in a direction opposite to the closing direction causing simultaneous screwable rotation of the second closure member from the container.

Abstract:
Source: US6074050A Disclosed is a replaceable ink container for providing ink to an ink–jet printing system. The

ink container includes a pressure vessel for pressurizing ink. The ink container has a non−operating state and an operating state. Within the operating state, the pressure vessel has an internal gauge pressure maintained within an operating range so that pressurized ink is provided to the printing system. The ink container also includes a gas vent apparatus communicating between an inside surface of the pressure vessel and an outside atmosphere to allow continuous venting in both the operating and non−operating states. In one preferred embodiment the vent apparatus includes a porous member that is located between a pressurized region of the ink container and an outside atmosphere. This porous member provides a flow path for gas therethrough.

Abstract:
Source: GB1002403A 1,002,403. Viscose spinning. CHIMIOTEX S.A. July 22, 1963 [July 20, 1963]; No. 28981/63. Addition to 910,878. Heading B5B. The process of the parent Specification (wherein filaments of regenerated cellulose are produced by spinning a viscose having a viscosity of at least 150 poises at 15‹ C. and a gamma value of at least 45 and containing a cellulose having a degree of polymerization of at least 400 into an aqueous coagulating bath containing not more than 40 g./1. of. sulphuric acid and substantially free from zinc sulphate, in the presence of formaldehyde) is modified in that the coagulating bath contains 10 to 120 g./1. of sodium sulphate and not more than 1 percent by weight of zinc sulphate (calculated as the anhydrous salt) and in that neither the viscose nor the spinning bath contain formaldehyde. Also in that the coagulated viscose filaments formed in the spinning bath are subsequently passed through an aqueous intermediate bath containing a small proportion of a water−soluble aldehyde, and then through a regeneration bath consisting of a hot dilute aqueous solution of sulphuric acid. The proportion of spinning bath liquid carried by the filaments of coagulated viscose from the spinning bath is preferably reduced by hydroextraction, mangling or perforated rollers whose hollow interiors are maintained at subatmospheric pressure. The fall in the gamma value of the filaments during their passage from the spinning bath to the intermediate bath is thereby reduced and the proportion of adelhyde taken up by the filaments in the intermediate bath increased. The viscose used preferably contains at least 3 percent of cellulose and at least 1A5 percent of caustic soda and preferably has a gamma value of 55 to 90. The D.P. of the cellulose in the viscose is preferably higher than 500 and its viscosity at the moment of spinning higher than 400 poises at 15‹ C. The spinning bath preferably contains 8 to 40 g./1. of sulphuric acid. The temperature of the first bath is preferably between 5‹ and 40‹ C., especially between 8‹ and 30‹ C. The intermediate bath may be a cold dilute acid bath containing from 1 to 40 grams of a water−soluble aldehyde per litre. The concentration of sulphuric acid and sodium sulphate in the intermediate bath may be similar to that in the coagulating bath. The filaments may be drawn at a draw ratio of at least 2:1 and preferably at least 3:1 in the coagulating bath and/or in the regenerating bath and/or during their passage through the air between these two baths. Specifications 685,631, 711,642 and 720,173 also are referred to.

Abstract:
Source: US2006000616A An improved hydraulic downhole oil recovery system that incorporates an above ground unit and a submersible, reciprocating downhole pump unit. Water−based fluid, rather than hydraulic fluid, is responsible for actuating the reciprocating downhole pump unit. The water−based fluid is transferred through the system using coil, coil tubing. The system further relies upon coil exterior production tubing to provide exceptional advantage in deviated oil wells.

Abstract:
Source: EP2263738A2 Implantable devices for delivering drugs and other substances to locations within the body of a human or animal subject to treat or diagnose sinusitis and a variety of other disorders. The application includes implantable substance delivery devices that comprise reservoirs and barriers that control the rate at which substances pass out of the reservoirs. The delivery devices may be advanced into the body using guidewires, catheters, ports, introducers and other access apparatus. In some embodiments the delivery devices may be loaded with one or more desired substance before their introduction into the body. In other embodiments the delivery devices are loaded and/or reloaded with a desired substance after the delivery device has been introduced into the body.

Abstract:
Source: US2017071702A The present invention relates to endosseous implants and in particular, to screw form dental implants for implanting within bone. The bone implant is configured to be a self–drilling bone implant that is adept at condensing, collecting and distributing bone along all of the implant's surface and within the implantation site, to significantly increase the bone implant contact surface. The implant is configured to have a coronal portion and a body portion that are continuous with one another. The coronal portion is configured to have a smaller overall diameter than the overall diameter of said body portion. The body portion is fit with threading that facilitates the self–drilling and bone collection properties when the implant is rotates in both the clockwise and counterclockwise directions.

Abstract:
A diffuser for use with a wound retractor and configured to deliver gases includes an interface tube for connecting to a gases supply and a diffuser interface positioned at a proximal end of the interface tube, the diffuser interface configured for delivering gases received from the gases supply through the interface tube, and the diffuser interface comprising a diffusion mechanism configured to deliver gases in a diffusion direction. A wound retractor with an integrated diffuser is also disclosed. The wound retractor includes an upper ring, a lower ring, a sleeve extending between and connecting the upper ring to the lower ring, and an integrated diffuser interface having a gases inlet and a diffusion mechanism.

Abstract:
Automatically controlled apparatus for the condensate drainage from the pressurized gas reservoirs (11A–11F), particularly from the air receivers of the industrial vehicles, including a pneumatic member (40) designed for being automatically operated whenever the motor of the vehicle is stopped, a control system (30–35) connected to said pneumatic member, and a valve device (10A–10F) provided for each reservoir (11A–11F) from which the condensate has to be drained, each valve device (10A–10F) being operated by said control system in order to pass from the closed to the opened position and viceversa whenever the pneumatic member is operated, and including: a finned (262) cylindrical body (210); a frustum–conical drainage valve member (223); a valve stem (216) connected to and controlling said drainage valve member; and a cylindrical spline head (224) integral with the frustum–conical drainage valve member and promoting a smooth and noiseless operation of the valve device.

Abstract:
Consisting of a filling unit with a water inlet, a valve and a floating closure device. The valve is controlled by the float and has a stem that can be closed by the float. Inside there are two chambers, one to let water in and the second for the water to pass to the filler pipe of the tank. Closing of the stem by pivoting due to the float, causes reduced pressure in part of chamber 1 which opposes by the pressure of the mains supply a flexible annular body which expands, causing the valve to close completely.For application in the manufacture of valves for filling tanks or reservoirs.

Abstract:
Source: US7957061B This invention is a device for displaying three−dimensional images using an array of tilting microcolumns. It can create high−resolution, large−scale, moving, three−dimensional images that can be viewed by people in different locations, with full parallax, without special eyewear. Unlike currently available methods, this invention: does not require special eyewear, works for multiple viewers, provides parallax in all directions, does not have a very restrictive viewing zone, does not produce only transparent images, does not require coherent light, is scalable to large displays, does not require liquid movement to adjust lens shape, and does not require complex systems to individually control large numbers of lenses.

Abstract:
Source: GB442436A 20018. [Class 39 (i)] An indirectly heated cathode which is produced by the distillation of a vaporizable metal–for example by the azide or thermite process–is " formed " after the metal has been deposited on the body by a heating current flowing through the body, so that the normal heating means are not overloaded during the forming. In one construction the cathode body d, Fig. 1, comprises a spiral with spaces between the turns; leads x y allow a forming current to flow so that the normal heating filament a need not be used. During normal running the leads x, y may be connected to ensure an equipotential condition, where the cathode body is a tube the leads x, y are connected to the ends ; the forming current may be supplied by inducton to a coil so disposed within the envelope that the electrodes are not effected by this inductive effect and the coil may be of copper to be of greater conductivity than the platinum or nickel body. In other constructions the cathode d, Fig. 5a, and the normal heater a are at the foci of an elliptical reflector c, which as shown is a control electrode. The cathode is connected through a heat–frangible piece f to a wire forming the support for the grid, so that the forming current may be supplied independently of the heater a. At the end of the forming process a high current is sent through the body to fuse the piece f. As shown the anode b is in plate form not to obstruct the normal heating effect from the heater a. The reflector may be the anode or anode screen or independent reflectors may be used ; the magnesium gettering coating on the envelope may be used as the reflector or the latter may be outside the envelope and may be a coating thereon. These reflectors may be of copper or silver, or of nickel or molybdenum coated with copper or silver. Stiffening plates may be provided for the electrodes and reflectors or steatite c. spacers may position the cathode and heater at the foci of the reflectors. The magnetic effect of the heater may be reduced by parallel conductors or screens ; if the heater is raised to emission temperatures it is given a positive bias. The heater is given greater bulk than the cathode by carbon or metal coating, the latter being subsequently oxidized for insulation effect; or wire may be wound on the heater in different amounts along its length so as to be thicker near the middle, to obtain uniformity of heating of the heater. The heater may be made entirely of ceramic material, i.e. a silite rod or it may be of carbon. As applied to valves of the kind described in Specification 415,079 which contain two systems, in one construction the heater a, Fig. 7, for the lower cathode d<1> is prolonged and used to heat the upper cathode d ; the forming device is the same as described with reference to Fig. 5a. The cathode d of the upper system supports the lower anode b <1> ; the upper system is to work at saturation and acts as a high alternating current resistance. The heater a is connected to the anode b and through a resistance r to the grid c ; the upper control grid may serve as the heater. In a modification of this construction the heater a, Fig. 18, is in the form of a resistance wire and may act as the anode for the upper system ; the control electrode c acts as the elliptic reflector and is supplied with a voltage at 180 to anode voltage of the tube. The heater a may be of the oxides of aluminium, zirconium or magnesium. In other constructions the heater a may be of spiral form within which the cathode d is situated. In further constructions two cathodes d<1>, d<2>, Fig. 9a with surrounding grids and it may be screens are placed at the foci of one or within two reflectors, which may also be electrodes ; one cathode acts as the heater for the other, and " forming " means are provided for each.

Abstract:
Source: GB592263A 592,263. Discharge apparatus. WESTERN ELECTRIC CO., Inc. Jan. 13, 1944, No. 710. Convention date, Feb. 12, 1942. [Class 39 (i)] [Also in Group XXII] A discharge tube has a flat perforated grid on a supporting ring in engagement with the metal envelope, this ring thereby dividing the envelope into two compartments, one containing the anode and the other the cathode, both these electrodes being flat and parallel with the grid. In the form shown, a flat grid 42 composed of parallel wires 43 is supported on ring 41 carried by ring 40 between the flat anode 25 and the cathode surface 35 formed on the top cover of a nickel tube 33 containing a helix of aluminium oxide coated tungsten wire, this tube being supported from an outer magnetic shield 36 by three tangentially arranged resilient fingers 38. The cathode assembly is supported by flange 39 secured to the shield 36 and the lead 31. A similar grid 44 functioning as a screen is carried by a flanged cylinder 46 secured to leads 21, 22. The casing 15 is of iron or copper and the inter–electrode spacing is specified. The grid 42 may be formed by welding parallel fine wires to a ring 47 placed in a die block 53, Fig. 6, having an undercut recess 54 receiving a ram 55 which distorts ring 47 to the oval form shown (exaggerated) in Fig. 7. Only the part within the dotted line, Fig. 7, is required as the active grid, the rest being masked by supporting ring 41 clamped to the grid in a press, the two then being welded together.

Abstract:
Source: US2002013592A A device (1) for closing a canal–shaped anastomosis (2), between the aorta (3) and the pulmonary artery (4), which remained open after the birth of a person (6). It is formed by a closing element (8) that can be inserted using a catheter (7) and that has two seals (10) and (11) spaced apart from each other and connected via an elastic tension element (9). The two seals have a certain elasticity and in the usage position, cover or fill up the two mouths or ends of the anastomosis (2), located between the aorta (3) and the pulmonary artery (4). The seals (10) and (11) can be folded, so that they on the one hand fit into the catheter (7) and on the other hand, can be introduced through the anastomosis (2) and brought to the respective application position. Using an eyelet (16) that is arranged in the area of the entrance into an inner longitudinal cavity (12) of the device and a tension thread (17) that passes through it, the seating of the closing element can be corrected especially through altematingly activating the thread (17) and an obturator or tool.

Abstract:
Source: FR2362287A Pompe a vide a impulseur liquide. Dans le volume d'aspiration 10 tourne un rotor 2, creux avec des ajutages d'ejection 23, 25 a la peripherie et un orifice axial d'entree d'eau 22. Autour du rotor 2 une couronne 3 comporte des canaux de pompage 30 s'etendant de la peripherie interne ou ils sont jointifs, jusqu'a la peripherie externe. La rotation du rotor 2 provoque l'injection dans les canaux 30 de lames d'eau successives qui emprisonnent et entrainent vers la peripherie les gaz presents dans le volume de pompage 10 relie par la bride 13 au recipient a pomper. Application a l'extraction des incondensables des condenseurs de centrales thermiques. The vacuum pump is used for removing the uncondensable products from power station condensers. It operates immersed in a tank and has a horizontally positioned rotor (2). This has a central suction inlet (20) and discharges the air/water mix centrifugally through four side ports (23, 24, 25, 26). The rotor operates inside an annular ring (3) of nozzles, the uncondensables being discharged into these from the ports. The nozzles (30) are approx. tangential and a laminar spiral flow is set up from the inlet (33) to the outlet (34) of the nozzles. The uncondensables are discharged into a compartment for separation of the contained air and passed over baffles.

Abstract:
Source: GB712546A 712,546. Typewriters c. NATIONAL CASH REGISTER CO. March 17, 1952 [March 22, 1951], No. 6802/52. Class 100 (4) An inking arrangement for a type wheel or wheels comprises an ink containing shaft 25 for feeding ink to capillary channels of the type wheels formed of carbon plates 31, 32 and with a porous type–carrying rim 33, the carbon plates forming an ink–proof seal with the metal shaft and with metal members, e.g. gears 36 and collar 40, located on each side of the type wheels. One end of the shaft 25 is mounted on a stud 22 on a frame plate 21 and the other end is threaded to receive an ink–font 26 mounted through a hole in a plate 20. Radial holes 32a allow the ink to pass to the capillary channels of the type wheels. These channels may be formed as shown in Fig. 2, by a film of metal foil 47 containing cut–out channels 34 and is mounted between the plates 31, 32 by two thin layers of thermo–setting bonding material 46, 48 having similar channels 34 formed therein. The plates 31, 32 are formed from amorphous coke, or lamp black, and graphite powders pressed into shape, sintered into a rigid mass, and then impregnated with wax or resin. On one side of the wheeel is bonded a gear wheel 36 and the other side wears to form a seal with the adjacent gear wheel or end collar 40. The collar 40 urged by a spring 38 effects a pressure contact between the plates 31, 32, a carbon end collar 37, and the gears 36. The spring 38 is covered by an oil–resistant rubber sleeve 41 or a thin metal bellows welded to the collar 40 and ink–font 26. The metal bellows may also serve as the spring 38. In a modification, the capillary channels are formed in one of the carbon plates and attached by adhesive to the other plate. The channels may be radial, spiral or tortuous in shape.

Abstract:
Source: GB200620970A A device comprising one or more proximal and distal chambers separated by a selectively permeable membrane which has a restricted but not absolute restriction of porosity with respect to dissolved solutes. This device is designed to generate a solution with a reduction in the concentration of these solutes distal to this membrane by the processes of forward and/or reverse osmosis. Such devices can further utilize those solutes initially present on the proximal side of the membrane but which have crossed the membrane themselves so that they then act as osmotic drivers and so facilitate the further movement of solutes across the membrane.
