**Abstract**

(EP2713308)

A method and system for tracking moving objects (155) in a sequence of images (110). In one illustrative embodiment, a current image (128) in the sequence of images (110) is segmented into a plurality of segments (138). Segments in the plurality of segments (138) belonging to a same motion profile are fused together to form a set of master segments (142). A set of target segments (154) is identified from the set of master segments (142). The set of target segments (154) represent a set of moving objects (155) in the current image (128). A set of fingerprints (156) is created for use in tracking the set of moving objects (155) in a number of subsequent images (162) in the sequence of images (110).

**Abstract**

(EP2008167)

Techniques are described for managing the execution of programs on a plurality of computing systems, such as computing systems organized into multiple groups. A program execution service manages the program execution on behalf of multiple customers or other users, and selects appropriate computing systems to execute one or more instances of program, such as based in part on locations of one or more previously stored copies of the program from which copies of the program to execute may be acquired. For example, in some situations the selection of an appropriate computing system to execute an instance of a program is based in part on **physical** or logical **proximity** to other resources, such as stored copies of the program, executing copies of the program, and/or available computing systems.

**Abstract**

(EP0822861)

Combinations, called matrices with memories, of matrix materials with remotely addressable or remotely programmable recording devices that contain at least one data storage unit are provided. The matrix materials are those that are used in as supports in solid phase chemical and biochemical syntheses, immunoassays and hybridization reactions. The matrix materials may additionally include fluophors or other luminescent moieties to produce luminescing matrices with memories. The data storage units are non-volatile antifuse memories or volatile memories, such as EEPROMS, DRAMS or flash memory. By virtue of this combination, molecules and biological particles, such as phage and viral particles and cells, that are in **proximity** or in **physical** contact with the matrix combination can be labeled by programming the memory with identifying information and can be identified by retrieving the stored information. Combinations of matrix materials, memories, and linked molecules and biological materials are also provided. The combinations have a multiplicity of applications, including combinatorial chemistry, isolation and purification of target macromolecules, capture and detection of macromolecules for analytical purposes, selective removal of contaminants, enzymatic catalysis, cell sorting, drug delivery, chemical modification and other uses. Methods for electronically tagging molecules, biological particles and matrix support materials, immuoassays, receptor binding assays, scintillation **proximity** assays, non-radioactive **proximity** assays, and other methods are also provided.

Abstract

(EP1760716)

A drive apparatus of the present invention includes a recording/reproduction section and a drive control section. The drive control section at least performs a process including: performing an RMW process of reproducing data recorded in an original ECC cluster including the location specified by the recording instruction, modifying at least a portion of the reproduced data, and recording the **modified** data in a replacement ECC cluster; determining whether or not there is any **physical** sector, in which the reproduction of data has failed, in the original ECC cluster in the RMW process; and setting status information value in status information of replacement management information when it is determined that there is any **physical** sector, in which the reproduction of data has failed, in the original ECC cluster in the RMW process, the status information value indicating that there is any **physical** sector, in which the reproduction of data has failed, in the original ECC cluster, the status information indicating that the original ECC cluster is replaced with the replacement ECC cluster.

Abstract

(EP1193713)

A structure editing apparatus and a picture structure editing apparatus capable of modifying or correcting a structure created in advance with data having a range (segment) set as a structural unit while utilizing original structure information as much as possible are provided. Each apparatus includes a first designating unit designating an arbitrary segment in structure information as a target segment; a second designating unit designating an arbitrary position included in a range of the target segment; and a segment dividing unit dividing the range of the target segment into two segments, i.e., a first half segment and a second half segment with the position designated by the second designating unit set as a dividing position, and replacing the target segment by the two segments.

**Abstract**

(EP3180073)

Methods and systems for obtaining and analyzing electromyography responses of electrodes of an implanted neurostimulation lead for use neurostimulation programming are provided herein. System setups for neural localization and/or programming include a clinician programmer coupleable with a temporary or permanent lead implantable in a patient and at least one pair of EMG sensing electrodes minimally invasively positioned on a skin surface or within the

patient. The clinician programmer is configured to determine a plurality of recommended electrode configurations based on thresholds and EMG responses of the plurality of electrodes and rank the electrode configuration according to pre-determined criteria. The clinician programmer further includes graphical **user** interface on which the plurality of recommended electrode configurations are displayed for modification and/or selection by a clinician in programming an IPG or EPG coupled with the lead to apply a neurostimulation treatment according to the selected electrode configuration.

Abstract

(EP3230832)

A wearable gesture control interface apparatus is used to control a controllable device based on gestures provided by a **user**. The wearable gesture control interface apparatus includes (i) sensors configured to detect **user** orientation and movement and generate corresponding sensor data and (ii) a microcontroller configured to: sample the sensor data from the sensors, determine whether the sensor data from one of the sensors meets transmission criteria; and if the sensor data meets the transmission criteria, transmitting control data corresponding to all of the sensors to the controllable device.

Abstract

(EP0998714)

A system (1480) filters documents in a document set retrieved from a document **store** in response to a query. The system (1480) obtains (1830) a first set of logical forms based on a selected one of the query and the documents in the document set. The system (1480) obtains a second set of logical forms based on another of the query and the documents in the document set. The system (1480) then uses natural language processing techniques to modify (1832, 1834) the first logical forms to obtain a **modified** set of logical forms. The system (1480) filters (1836) documents in the document set based on a predetermined relationship between the **modified** set of logical forms and the second set of logical forms.

Abstract

(EP0254561)

A keyboardless-entry computer system includes a transparent input screen (18) that generates positional information when contacted by a stylus, and a display screen (20) mounted physically below the input screen such that a character that is displayed can be seen below the input screen. The system includes a computer (14) programmed to compile the positional information into Strokes, to calculate Stroke characteristics, and then compare the Stroke characteristics with those stored in a database in order to recognise the symbol drawn by the stylus. Key features of the system are: (A) transparent position sensing subsystem; (B) underlying display on which to mimic drawing of sensed positions and to shown characters or symbols; (C) means to convert sensed positions first into plotted Points and then into recognised characters or symbols; and (D) means to "learn" to associate sensed input positions with a character or symbol.

Abstract

(EP1461753)

A method and system for assisting and expediting an organization toward higher levels of the Capability Maturity Model (CMM). The invention provides a method for producing a more mature product. The method comprises the managing of an organization developing the product, whereby management comprises managing organizational personnel and implementing a product improvement process. The method may comprise managing a product development project and the delivery of the product. Actions undertaken during the organizational management affects implementation of the project and delivery managements, and the actions undertaker during the project and delivery management affect implementation of the organizational management. The method may be implemented using electronic hardware and software, locally or over a network such as an intranet or the Internet (12). The method may be implemented using a document management system to administer files and assist a **user** in the creation of documents related to the steps in the method. The invention uses WebDAV-based communication to coordinate access to multiple document repositories.

Abstract

(EP1097588)

A method and apparatus for combining video frame sequences with a video display of an interactive program guide (IPG). The apparatus comprises a plurality of compositors that combine background information, video frame sequences and program guide graphics into a single video frame sequence. The sequence is then digitally encoded to form an MPEG-like bitstream. The same background information and informational video is composited with a different program guide graphic to form another video sequence that is also encoded. A plurality of such sequences are produced with each sequence having a different program guide graphic. Each sequence is encoded and then multiplexed into a transport stream such that all the encoded sequences are transmitted to a subscriber's terminal using a single transport stream. As such, the subscriber can transit from one program guide to the next without interruption of the background or video display as the

program guide graphic is changed.

**Abstract**

(EP0822990)

The present invention relates to a novel drug discovery system for generating and screening molecular diversity. The system provides methods for mixing and cloning genetic materials from a plurality of species of organisms in combinatorial gene expression libraries to generate novel metabolic pathways and classes of compounds. The system also involves methods for pre-screening or identifying for host organisms containing a library that are capable of generating such novel pathways and compounds. The host organisms may be useful in drug screening for particular diseases, and in commercial production of compounds of interest. The methods of the invention are also useful in preserving the genomes of organisms that are known or prospective sources of drugs.

Abstract

(US20130086365)

A pool of available **physical** registers are provided for architected registers, wherein operations are performed that activate and deactivate selected architected registers, such that the deactivated selected architected registers need not retain values, and **physical** registers can be deallocated to the pool, wherein deallocation of **physical** registers is performed after a last-use by a designated last-use instruction, wherein the last-use information is provided either by the last-use instruction

or a prefix instruction, wherein reads to deallocated architecture registers return an architected default value.

Abstract

(EP3053630)

A lacrosse head pocket and a related method of manufacture are provided to facilitate consistent, repeatable and/or custom manufacture of lacrosse equipment. The pocket can be constructed from multiple different sections joined with one another, or can be knitted, weaved or otherwise assembled on an automated assembly machine from strands, and/or can be formed as a unitary textile material having regions/sections with different **physical** and/or mechanical properties. The pocket can be integrally molded within portions of a lacrosse head to eliminate manually constructed connections between the pocket and lacrosse head. The lacrosse head can be integrally molded with a lacrosse handle to provide a one-piece unitary lacrosse stick. Related methods of manufacturing also are provided.
